11
12   Introductory text

13   **Introduction**

14   This supporting information is for readers who wish to see more details than are necessary to
15   understand the results as presented in the main text of the article. For example, the LSMPs (large scale
16   meteorological patterns) for the heat waves of the two types are shown, similar to what is shown in
17   LG2016. The longitude by latitude regions in which the LSMPi and cluster indices are calculated are
18   stated in the main text, but a reader wishing to visualize them can do so here. The LSMPs for the ERA-
19   Interim data are also shown in case a reader wants to compare that (shorter period with few events)
20   reanalysis against the NCEP-NCAR reanalysis used in data shown in the main text. As shown by LG2016,
21   the two reanalyses match in terms of LSMP and cluster type. The differences between historical and
22   future climate means needed to understand the preference for cluster type 2 in the future are
23   adequately described in the text, but details are shown here for the CCSM4 model. The Generalized
24   Pareto shape parameter is often paired with the scale parameter; the latter was shown in the text while
25   the former was deemed inconclusive and thus not discussed in the text; shape is shown here for
26   completeness. Trends are shown in the distributions of LSMPi values between the first and last 20 year
27   periods for the RCP8.5 scenario which might interest some readers, but these were not discussed in the
28   text. Historical simulation and reanalysis LSMPs of temperature anomaly at 850 hPa for readers who
29   want a visual depiction of the LSMP metrics defined in section 2.7 and presented in section 3.1 of the
30   main text. Only 5 of the 13 models are shown; also shown are the boundaries of the small domain for
31   the bias and percent error calculations.

47

48

49
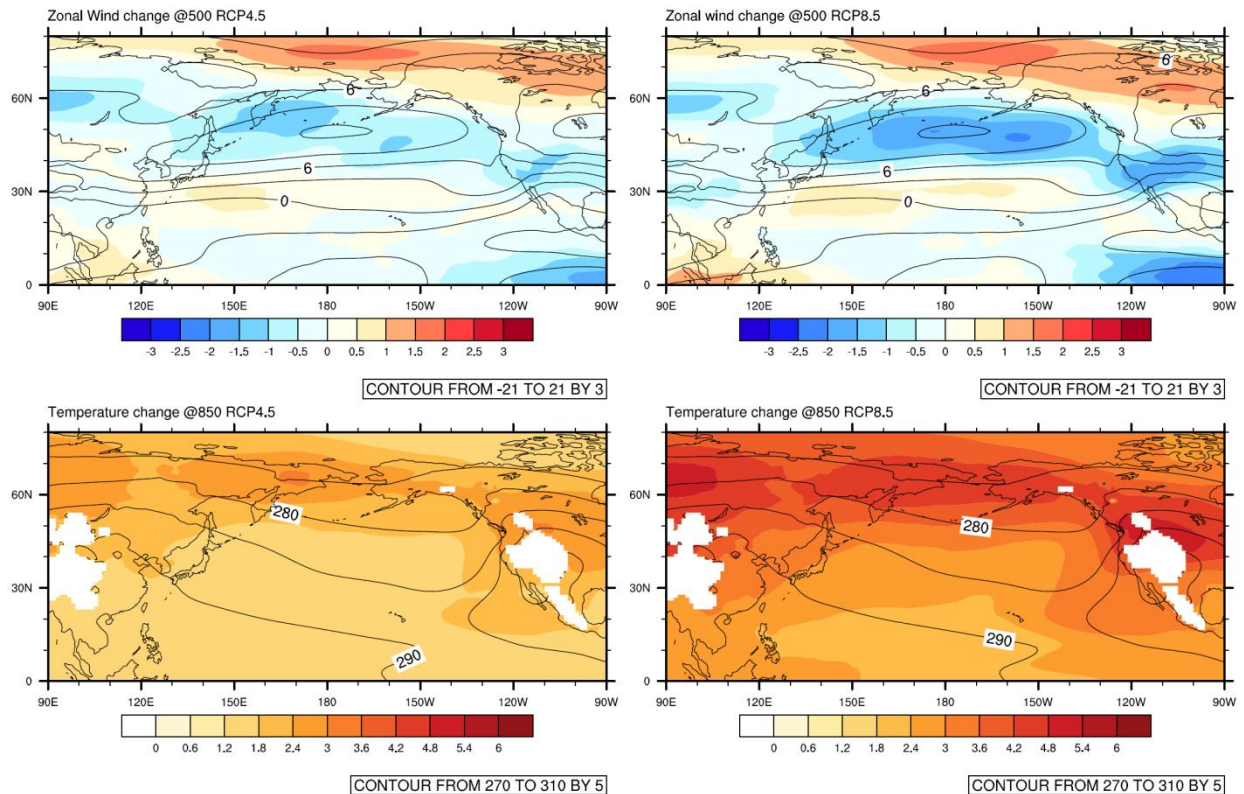

50
51 **Figure S9**. The panels show the change of summer climatology (averaged over June-September)
52 from historical to future simulations by CCSM4 at the 500 hPa level of: zonal mean wind (top)
53 and the 850hPa temperature (bottom). The difference is future summer minus historical
54 summer averages. The shading varies between upper and lower panels. The historical
55 climatology is from 1951-2000 data and future climatology is from 2051-2100 for two RCP
56 scenarios. The left side panels are the RCP4.5 changes and right side panels are the RCP8.5
57 changes. These plots help interpret changes to the cluster strengths and the number of heat
58 waves in 'Fh' simulations. For example, where these climatological mean changes match up
59 well with the anomaly patterns of a particular cluster, that cluster would occur more frequently
60 in the future. The patterns of the lower row have a warm anomaly over Canada that more
61 closely matches the key region for cluster 2 (figures S2 and S6) than cluster 1 (figures S1 and
62 S5).
63
64

6
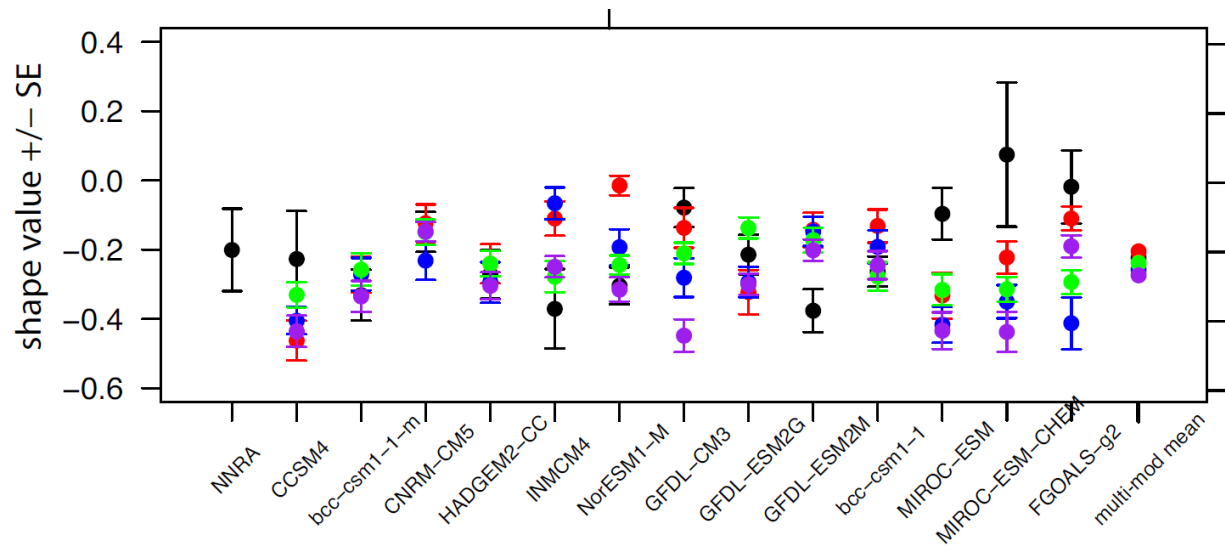

Figure S10. Generalized Pareto shape parameter values for model and reanalysis data LSMPi >1. The black dots are Hh, red dots are Ff (RCP4.5), blue dots are Ff (RCP8.5), green dots are Fh (RCP4.5) and purple dots are Fh (RCP8.5). The dots are the mean and the range shown is the 95% confidence interval.

7

70
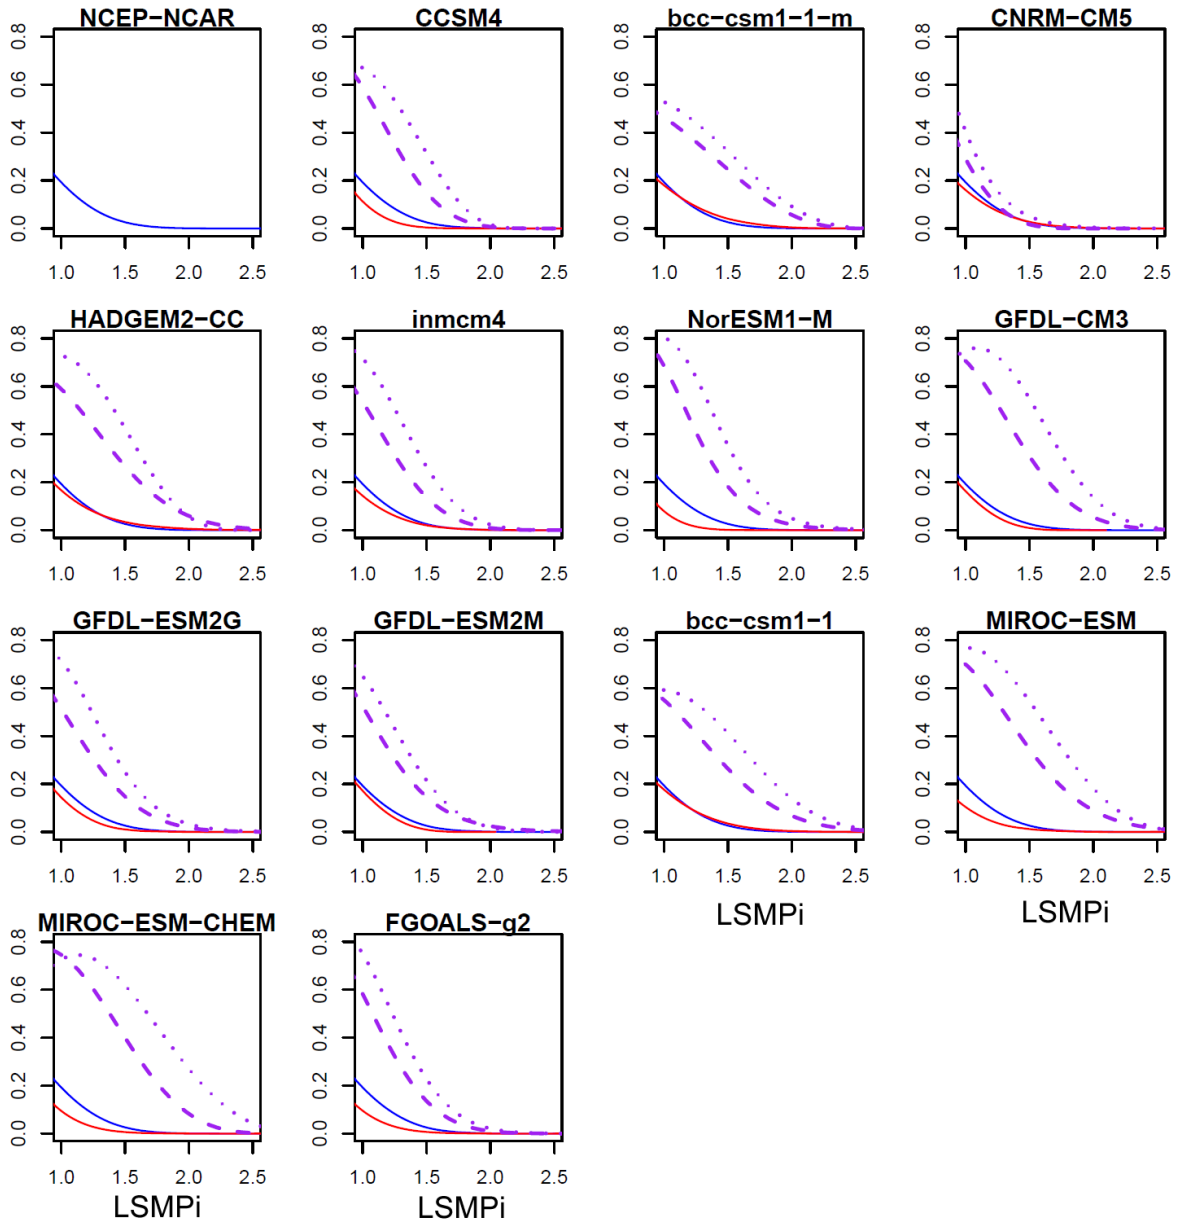

Figure S11. Distribution of the summer days for abscissa values LSMPi >1. The blue line indicates the NCEP-NCAR reanalysis. The red curve indicates the CMIP5_Hh model simulations. The dashed purple curve indicates the 2061-2080 distribution of the CMIP5_Fh for RCP8.5 and the purple dotted curve indicates the 2081-2100 distribution of the CMIP5_Fh for RCP 8.5.

81

82
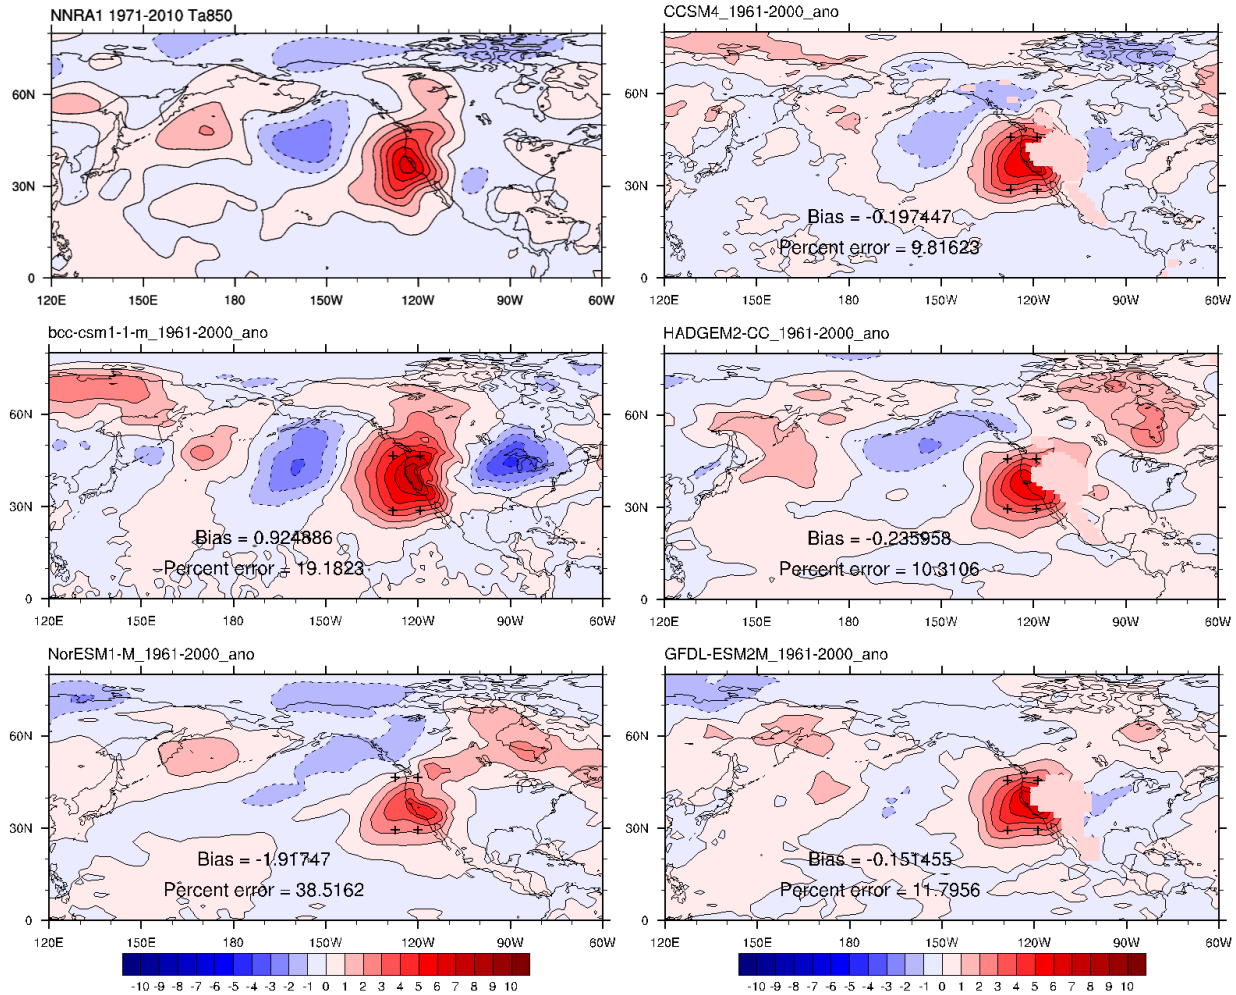

83

84   **Figure S12**. Comparisons of the LSMP of temperature anomaly at 850hPa for the NCEP-NCAR

85   reanalysis (upper left panel) and five of the models. The model plots include the bias and

86   percent error information from the region bounded by the '+' symbols when compared with

87   this reanalysis ensemble mean. The error metrics are not calculated where a model does not

88   have data (seen over the Rocky Mountains for the three models on the right column).

28   **Table S2**. This table displays the number of events for the CMIP5_Hh, CMIP5_Ff (RCP4.5) and

29   CMIP5_Fh (RCP4.5) simulations including separate totals for cluster types one and two. The

30   sum of clusters one and two may be less than the total number due to those events determined

31   to be type mixed. (See the main text for information about the mixed designation.) Unlike the

32   main text, this table only uses one simulation even when a model has multiple members of

33   their ensemble simulations. Red color indicates results where the RCP4.5 total number of

34   events exceeds the corresponding number for RCP8.5.

35
