

Introduction to Fortran 90

F. Salvatore I. Baccarelli G. Amati

CINECA Roma - SCAI Department

Roma, 20-23 January 2014

Part I

A Fortran Survey 1

Program main unit, source formats, comments, declarations and instructions. Fundamental operators, expressions, conditional constructs, loops, functions: arguments passing, intent, interface, intrinsic and external functions. Modules: contains and use. Intrinsic types: integer, real, complex, logical, and parameter. I/O base.

Introduction

Fortran Basics

More Fortran Basics

Integer Types and Iterating

More on Compiling and Linking

Homeworks

- ▶ Developed in the 50s among the earliest high level languages (HLL)
- ▶ Widely and rapidly adopted in the area of numerical, scientific, engineering and technical applications
- ▶ First standard in 1966: Fortran 66
 - ▶ The first of all programming language standards
- ▶ Second standard in 1978: Fortran 77
- ▶ Third standard in 1991: Fortran 90
 - ▶ Adds new, modern features such as structured constructs, array syntax and ADT
 - ▶ Extended and revised in 1997: Fortran 95
 - ▶ Further extended with published Technical Reports
- ▶ Fourth standard in 2004: Fortran 2003
 - ▶ Major revision, incorporates TRs, adds many new features (OO!), still not fully supported
- ▶ Fifth standard in 2010: Fortran 2008

- ▶ Strongly oriented to *number crunching*
- ▶ Efficient language, highly optimized code
 - ▶ Basic data types and operators mapping "naturally" to CPUs
 - ▶ Translated by a compiler to machine language
 - ▶ Language rules allow for aggressive, automatic optimization
 - ▶ Facilities to build new data types from the basic ones
 - ▶ Flexible flow control structures mapping the most common numerical computing use cases
- ▶ Scientific computing specialized syntax
 - ▶ A wealth of math data types and functions available as intrinsics of the language
 - ▶ Compact, readable array syntax to operate on many values as a whole

► Why Fortran is bad

- Current standard embodies four different language versions,...
- ... all of them still alive in legacy codes
- Non-numeric computing in Fortran is a real pain
- There are more C than Fortran programmers
- GUI and DB accesses are best programmed in C
- C99 partly addressed numerical computing needs

▶ Why Fortran is bad

- ▶ Current standard embodies four different language versions,...
- ▶ ... all of them still alive in legacy codes
- ▶ Non-numeric computing in Fortran is a real pain
- ▶ There are more C than Fortran programmers
- ▶ GUI and DB accesses are best programmed in C
- ▶ C99 partly addressed numerical computing needs

▶ Why Fortran is good

- ▶ Fortran is highly tuned for numerical computation
- ▶ Fortran is older and more “rigid” than C, compilers optimize better
- ▶ Much better than C at managing user defined data types
- ▶ Object-oriented features are now part of the language
- ▶ Provides facilities for interoperability with C and other languages

- ▶ Teach you the fundamentals of modern Fortran
- ▶ For both reading (old and new) and writing (new) programs
- ▶ Showing common idioms
- ▶ Illustrating and demonstrating many of the extensions introduced in the more recent standards
- ▶ Illustrating best practices
- ▶ Blaming bad ones
- ▶ Making you aware of the typical traps

- ▶ Teach you the fundamentals of modern Fortran
- ▶ For both reading (old and new) and writing (new) programs
- ▶ Showing common idioms
- ▶ Illustrating and demonstrating many of the extensions introduced in the more recent standards
- ▶ Illustrating best practices
- ▶ Blaming bad ones
- ▶ Making you aware of the typical traps
- ▶ You'll happen to encounter things we didn't cover, but it will be easy for you to learn more... or to attend a more advanced course!
- ▶ A course is not a substitute for a reference manual or a good book!

- ▶ Teach you the fundamentals of modern Fortran

  write(*,*) 'Real roots:', x1, x2

end program second_degree_eq
```

- ▶ Fortran code is organized in program units
 - ▶ Main program
 - ▶ Procedures (subroutines and functions)
 - ▶ Modules
 - ▶ More on this later...

- ▶ Fortran code is organized in program units
 - ▶ Main program
 - ▶ Procedures (subroutines and functions)
 - ▶ Modules
 - ▶ More on this later...

- ▶ The main program (one, and only one!) can't be dispensed with
 - ▶ It's called automatically to execute the program
 - ▶ An optional `program program-name` can appear at the beginning
 - ▶ An `end` statement must terminate it, optionally followed by `program` or `program program-name`

- ▶ Fortran code is organized in program units
 - ▶ Main program
 - ▶ Procedures (subroutines and functions)
 - ▶ Modules
 - ▶ More on this later...
- ▶ The main program (one, and only one!) can't be dispensed with
 - ▶ It's called automatically to execute the program
 - ▶ An optional `program program-name` can appear at the beginning
 - ▶ An `end` statement must terminate it, optionally followed by `program` or `program program-name`
- ▶ Best practice: always mark unit beginning and ending with its type and name
 - ▶ Makes your readers (including you) happier

! roots of a 2nd degree equation with real coefficients

```
program second_degree_eq
  implicit none
  real :: delta
  real :: x1, x2
  real :: a, b, c

  print *, 'Solving ax^2+bx+c=0, enter a, b, c:'
  read (*,*) a, b, c

  delta = sqrt(b**2 - 4.0*a*c)
  x1 = -b + delta
  x2 = -b - delta
  x1 = x1/(2.0*a)
  x2 = x2/(2.0*a)

  write(*,*) 'Real roots:', x1, x2

end program second_degree_eq
```

- ▶ `real :: x1, x2` declares two variables
 - ▶ Named memory locations where values can be stored
 - ▶ Declared by specifying a data type, an optional attribute list, and a comma-separated list of names
 - ▶ On most CPUs (notably x86), `real` means that `x1` and `x2` host IEEE single precision (i.e. 32 bits) floating point values

- ▶ **real :: x1, x2** declares two variables
 - ▶ Named memory locations where values can be stored
 - ▶ Declared by specifying a data type, an optional attribute list, and a comma-separated list of names
 - ▶ On most CPUs (notably x86), **real** means that **x1** and **x2** host IEEE single precision (i.e. 32 bits) floating point values
- ▶ A legal *name* must be used for a variable:
 - ▶ Permitted characters: **a-z, A-Z, 0-9, _**
 - ▶ The first one cannot be a digit (e.g. **x1** is a valid name, **1x** is not)
 - ▶ At most 31 characters are permitted (63 in Fortran 2003)
 - ▶ A good advice: do not exceed 31 characters in a name

- ▶ **real :: x1, x2** declares two variables
 - ▶ Named memory locations where values can be stored
 - ▶ Declared by specifying a data type, an optional attribute list, and a comma-separated list of names
 - ▶ On most CPUs (notably x86), **real** means that **x1** and **x2** host IEEE single precision (i.e. 32 bits) floating point values
- ▶ A legal *name* must be used for a variable:
 - ▶ Permitted characters: **a-z, A-Z, 0-9, _**
 - ▶ The first one cannot be a digit (e.g. **x1** is a valid name, **1x** is not)
 - ▶ At most 31 characters are permitted (63 in Fortran 2003)
 - ▶ A good advice: do not exceed 31 characters in a name
- ▶ Beware: Fortran is CaSe insenSITIVE!

- ▶ By default, Fortran assumes that variables not appearing in any declaration statement are implicitly declared as follows:

- ▶ By default, Fortran assumes that variables not appearing in any declaration statement are implicitly declared as follows:
 - ▶ Variables whose name starts with **A - H** and **O - Z** are reals

- ▶ By default, Fortran assumes that variables not appearing in any declaration statement are implicitly declared as follows:
 - ▶ Variables whose name starts with **A - H** and **O - Z** are reals
 - ▶ Variables whose name starts with **I, J, K, L, M, N** are integers

- ▶ By default, Fortran assumes that variables not appearing in any declaration statement are implicitly declared as follows:
 - ▶ Variables whose name starts with **A - H** and **O - Z** are reals
 - ▶ Variables whose name starts with **I, J, K, L, M, N** are integers
- ▶ Best practice: it is strongly recommended to turn off implicit declarations with **implicit none**, at the beginning of each program unit
 - ▶ Improves readability and clarity: each variable has its type declared
 - ▶ Mistyped names can be caught by the compiler as undeclared variables

! roots of a 2nd degree equation with real coefficients

```
program second_degree_eq
  implicit none
  real :: delta
  real :: x1, x2
  real :: a, b, c

  print *, 'Solving ax^2+bx+c=0, enter a, b, c:'

- ▶ Fortran lets you write programs in a high-level, human-readable language
- ▶ Computer CPUs do not directly understand this language
- ▶ You need to translate your code into machine-level instructions for your CPU architecture
- ▶ **Compilers take care of that translation and generate machine code that can be actually executed by a CPU**

- ▶ Compilers are sophisticated tools, made up of many components
- ▶ When compiler is invoked to generate executable code, three main steps are performed:
 1. parsing of source files, various kinds of analysis and transformations, optimization and *assembly* files creation
 2. machine-code generation and object file creation
 - ▶ an object file is an organized collection of all symbols (variables, functions...) used or referenced in the code
 3. linking and executable creation
- ▶ Options are provided to execute each step separately, take a look at the manual of your favourite compiler, there's a lot to learn!

Compile your first Fortran program !

- ▶ GNU compiler collection includes **gfortran** compiler, supporting Fortran 95 and several features of the 2003 standard (GNU 4.8)

Compile your first Fortran program !

- ▶ GNU compiler collection includes **gfortran** compiler, supporting Fortran 95 and several features of the 2003 standard (GNU 4.8)
- ▶ Many more available on the market (Intel, PGI, Pathscale, IBM XL Fortran, Sun Studio Fortran, Lahey, NAG, etc)

- ▶ Nested `ifs` can be a problem
 - ▶ `else` marries innermost `if () then/end if` pair
 - ▶ Proper indentation is almost mandatory to sort it out

- ▶ Nested **ifs** can be a problem
 - ▶ **else** marries innermost **if () then/end if** pair
 - ▶ Proper indentation is almost mandatory to sort it out
- ▶ What's this **write(0,*)** stuff?
 - ▶ **write()** and **read()** let you specify an output (input) file 'handle' called a unit
 - ▶ Unit 0 is usually connected to a special file, mandatory for error messages to the terminal (e.g. UNIX standard error)
 - ▶ By the way, **write(*,*)** is a system independent idiom for what you'll often find written as **write(6,*)**
 - ▶ And **read(*,*)** is a system independent idiom for what you'll often find written as **read(5,*)**
 - ▶ And **stop error-message** is equivalent to: **write(0,*) error-message**
stop

- ▶ Nested **ifs** can be a problem
 - ▶ **else** marries innermost **if () then/end if** pair
 - ▶ Proper indentation is almost mandatory to sort it out
- ▶ What's this **write(0,*)** stuff?
 - ▶ **write()** and **read()** let you specify an output (input) file 'handle' called a unit
 - ▶ Unit 0 is usually connected to a special file, mandatory for error messages to the terminal (e.g. UNIX standard error)
 - ▶ By the way, **write(*,*)** is a system independent idiom for what you'll often find written as **write(6,*)**
 - ▶ And **read(*,*)** is a system independent idiom for what you'll often find written as **read(5,*)** 
 - ▶ And **stop error-message** is equivalent to: **write(0,*) error-message**
stop
- ▶ Best practice: if your program has to fail, always have it fail in a controlled way

- ▶ Let's give names to `if` constructs:

```
no2nd: if (a == 0.0) then
  nolst: if (b == 0.0) then
    no0th: if (c == 0.0) then
      write(0,*) 'A trivial identity!'
    else no0th
      write(0,*) 'Plainly absurd!'
    end if no0th
  else nolst
    write(0,*) 'Too simple problem!'
  end if nolst
  stop
end if no2nd
```

- ▶ Let's give names to `if` constructs:

```
no2nd: if (a == 0.0) then
  nolst: if (b == 0.0) then
    no0th: if (c == 0.0) then
      write(0,*) 'A trivial identity!'
    else no0th
      write(0,*) 'Plainly absurd!'
    end if no0th
  else nolst
    write(0,*) 'Too simple problem!'
  end if nolst
  stop
end if no2nd
```

- ▶ Giving names to constructs makes program logic more explicit

- ▶ Let's give names to `if` constructs:

```
no2nd: if (a == 0.0) then
  nolst: if (b == 0.0) then
    no0th: if (c == 0.0) then
      write(0,*) 'A trivial identity!'
    else no0th
      write(0,*) 'Plainly absurd!'
    end if no0th
  else nolst
    write(0,*) 'Too simple problem!'
  end if nolst
  stop
end if no2nd
```

- ▶ Giving names to constructs makes program logic more explicit
- ▶ Names are for readability purposes only, do not enforce pairing rules

- ▶ Let's give names to `if` constructs:

```
no2nd: if (a == 0.0) then
  nolst: if (b == 0.0) then
    no0th: if (c == 0.0) then
      write(0,*) 'A trivial identity!'
    else no0th
      write(0,*) 'Plainly absurd!'
    end if no0th
  else nolst
    write(0,*) 'Too simple problem!'
  end if nolst
  stop
end if no2nd
```

- ▶ Giving names to constructs makes program logic more explicit
- ▶ Names are for readability purposes only, do not enforce pairing rules
- ▶ **Best practice:** always give names to constructs which span many lines of code or are deeply nested

- ▶ The one on the left, is the statement $Z(I) = Y + W(I)$
- ▶ The one in the middle, is an IBM punch card reader
- ▶ The one on the right, is a complete Fortran source program
- ▶ But you'll only encounter these in museums, nowadays

C ROOTS OF A 2ND DEGREE EQUATION WITH REAL COEFFICIENTS

```
PROGRAM EQ2DEG
```

```
IMPLICIT NONE
```

```
REAL DELTA
```

```
REAL RP
```

```
REAL A, B, C
```

```
PRINT *, 'SOLVING AX^2+BX+C=0, ENTER A, B, C: '
```

```
READ(*,*) A, B, C
```

```
DELTA = B*B - 4.0*A*C
```

```
IF (DELTA.LT.0.0) STOP 'NO REAL ROOTS!'
```

```
DELTA = SQRT(DELTA) / (2.0*A)
```

```

Homeworks

A Fortran Program is Made of: I

- ▶ **Comments**
 - ▶ Compiler disregards them, but humans do not
 - ▶ Please, use them
 - ▶ Do not abuse them, please
- ▶ **Program units**
 - ▶ One, at least: **program**
 - ▶ Some of them (functions) are intrinsic to the language
- ▶ **Variables**
 - ▶ Named memory location you can store values into
 - ▶ Must be declared
- ▶ **Variables declarations**
 - ▶ Give name to memory location you can store values into
 - ▶ An initial value can be specified

A Fortran Program is Made of: II

- ▶ Expressions
 - ▶ Compute values to store in variables
 - ▶ Compute values to pass to functions and statements
- ▶ Statements
 - ▶ Units of executable work
 - ▶ Whose execution can be controlled by other constructs
- ▶ **if** statements and constructs
 - ▶ Allow for conditional and alternative execution
 - ▶ For both single statements and blocks of

- ▶ Use free source form
- ▶ **implicit none** statement
 - ▶ Turn off implicit declarations
- ▶ Use proper indentation
 - ▶ Compilers don't care about
 - ▶ Readers visualize flow control
- ▶ Give names to complex control structures, readers will appreciate
- ▶ Do non-regression testing
 - ▶ Whenever functionalities are added
 - ▶ Whenever you rewrite a code in a different way
- ▶ Fail in a controlled way
 - ▶ Giving feedback to humans

function rect(t, tau) !generalized rectangular function, useful in DSP
  implicit none
  real :: rect
  real :: t, tau
  real :: abs_t, half_tau
  real, external :: theta

  abs_t = abs(t)
  half_tau = 0.5*tau
  rect = 0.5
  if (abs_t /= half_tau) rect = theta(half_tau-abs_t)
end function rect
```

- ▶ The `parameter` attribute is used to declare named constants
 - ▶ i.e. variables that cannot be modified after initialization (compiler will bark if you try)

- ▶ The `parameter` attribute is used to declare named constants
 - ▶ i.e. variables that cannot be modified after initialization (compiler will bark if you try)
- ▶ In initialization expressions:

- ▶ The `parameter` attribute is used to declare named constants
 - ▶ i.e. variables that cannot be modified after initialization (compiler will bark if you try)
- ▶ In initialization expressions:
 - ▶ only constants (possibly other `parameters`) can be used

- ▶ The `parameter` attribute is used to declare named constants
 - ▶ i.e. variables that cannot be modified after initialization (compiler will bark if you try)
- ▶ In initialization expressions:
 - ▶ only constants (possibly other `parameters`) can be used
 - ▶ only intrinsic operators or functions are allowed

- ▶ The `parameter` attribute is used to declare named constants
 - ▶ i.e. variables that cannot be modified after initialization (compiler will bark if you try)
- ▶ In initialization expressions:
 - ▶ only constants (possibly other `parameters`) can be used
 - ▶ only intrinsic operators or functions are allowed
- ▶ Best practice: always give name to constants
 - ▶ Particularly if unobvious, like `1.0/137.0`
 - ▶ It also helps to centralize updates (well, not for π)

- ▶ Try it now!
- ▶ Best practices
 - ▶ If you have a set of related procedures, always make a module
 - ▶ If you have a single procedure, just to tame code complexity, called by a single program unit, a module could be overkill

use Modules, Instead!

- ▶ Modules are the Fortran way to complete and robust management of sets of related routines and more
- ▶ Interfaces are automatically defined for each procedure a module contains
- ▶ To use **theta ()**, **sinc ()**, and **rect ()** in a program unit:
 - ▶ just add a **use dsp** statement
 - ▶ before you declare anything else in the unit
- ▶ Try it now!
- ▶ Best practices
 - ▶ If you have a set of related procedures, always make a module
 - ▶ If you have a single procedure, just to tame code complexity, called by a single program unit, a module could be overkill
- ▶ But there is a lot more to say about modules

- ▶ A nice colleague handed you the `dsp` module...
- ▶ but you prefer your own version of `rect ()` , which returns 1 on borders:
 - ▶ don't change the module source

- ▶ A nice colleague handed you the `dsp` module...
- ▶ but you prefer your own version of `rect ()`, which returns 1 on borders:
 - ▶ don't change the module source
 - ▶ **use `dsp, only : theta, sinc`** and keep using your own `rect ()`

- ▶ A nice colleague handed you the `dsp` module...
- ▶ but you prefer your own version of `rect ()`, which returns 1 on borders:
 - ▶ don't change the module source
 - ▶ **use `dsp, only : theta, sinc`** and keep using your own `rect ()`
- ▶ or you already have a function called `theta ()`, called all over your code, and don't want to change it:

- ▶ A nice colleague handed you the `dsp` module...
- ▶ but you prefer your own version of `rect ()`, which returns 1 on borders:
 - ▶ don't change the module source
 - ▶ `use dsp, only : theta, sinc`
and keep using your own `rect ()`
- ▶ or you already have a function called `theta ()`, called all over your code, and don't want to change it:
 - ▶ rename the `theta ()` function in `dsp` like this:
`use dsp, heaviside=>theta`

- ▶ A nice colleague handed you the `dsp` module...
- ▶ but you prefer your own version of `rect ()` , which returns 1 on borders:
 - ▶ don't change the module source
 - ▶ `use dsp, only : theta, sinc`
and keep using your own `rect ()`
- ▶ or you already have a function called `theta ()` , called all over your code, and don't want to change it:
 - ▶ rename the `theta ()` function in `dsp` like this:
`use dsp, heaviside=>theta`
- ▶ or maybe both:

- ▶ A nice colleague handed you the `dsp` module...
- ▶ but you prefer your own version of `rect ()`, which returns 1 on borders:
 - ▶ don't change the module source
 - ▶ `use dsp, only : theta, sinc`
and keep using your own `rect ()`
- ▶ or you already have a function called `theta ()`, called all over your code, and don't want to change it:
 - ▶ rename the `theta ()` function in `dsp` like this:
`use dsp, heaviside=>theta`
- ▶ or maybe both:
 - ▶ `use dsp, only : heaviside=>theta, sinc`

```
function rect(t, tau)
  implicit none
  real :: rect
  real, intent(in) :: t, tau
  real :: abs_t, half_tau

  abs_t = abs(t)
  half_tau = 0.5*tau
  rect = 0.5
  if (abs_t /= half_tau) rect = theta(half_tau-abs_t)
end function rect
```

- ▶ What if `rect ()` is passed a negative argument for `tau`?

```
function rect(t, tau)
  implicit none
  real :: rect
  real, intent(in) :: t, tau
  real :: abs_t, half_tau

  abs_t = abs(t)
  half_tau = 0.5*tau
  rect = 0.5
  if (abs_t /= half_tau) rect = theta(half_tau-abs_t)
end function rect
```

- ▶ What if `rect ()` is passed a negative argument for `tau`?
 - ▶ Wrong results

```
function rect(t, tau)
  implicit none
  real :: rect
  real, intent(in) :: t, tau
  real :: abs_t, half_tau

  abs_t = abs(t)
  half_tau = 0.5*tau
  rect = 0.5
  if (abs_t /= half_tau) rect = theta(half_tau-abs_t)
end function rect
```

- ▶ What if `rect ()` is passed a negative argument for `tau`?
 - ▶ Wrong results
- ▶ Taking the absolute value of `tau` it's a possibility

```
function rect(t, tau)
  implicit none
  real :: rect
  real, intent(in) :: t, tau
  real :: abs_t, half_tau

  abs_t = abs(t)
  half_tau = 0.5*tau
  rect = 0.5
  if (abs_t /= half_tau) rect = theta(half_tau-abs_t)
end function rect
```

- ▶ What if `rect ()` is passed a negative argument for `tau`?
 - ▶ Wrong results
- ▶ Taking the absolute value of `tau` it's a possibility
- ▶ But not a good one, because:
 - ▶ a negative rectangle width is nonsensical
 - ▶ probably flags a mistake in the calling code
 - ▶ and a zero rectangle width is also a problem

```
function rect(t, tau)
  implicit none
  real :: rect
  real, intent(in) :: t, tau
  real :: abs_t, half_tau

  if (tau <= 0.0) stop 'rect() non positive second argument'
  abs_t = abs(t)
  half_tau = 0.5*tau
  rect = 0.5
  if (abs_t /= half_tau) rect = theta(half_tau-abs_t)
end function rect
```

- ▶ A known approach...

```
function rect(t, tau)
  implicit none
  real :: rect
  real, intent(in) :: t, tau
  real :: abs_t, half_tau

  if (tau <= 0.0) stop 'rect() non positive second argument'

- ▶ No easy way to share variables among program units
 - ▶ To share you had to use **common** statements
 - ▶ And type in variable types and **common** statements in each unit
 - ▶ And the smallest mistake can turn into a nightmare
- ▶ Bottom line:
 - ▶ Is **common** good or bad? The jury is still out
 - ▶ We'll not cover them, but you'll encounter them
 - ▶ Read the fine print, or better switch to modules, they are **way much better**

- ▶ You are lucky, and inherit a 4000 lines of code library, coming from the dark ages
 - ▶ Tested and tried

Refurbishing Old Code

- ▶ You are lucky, and inherit a 4000 lines of code library, coming from the dark ages
 - ▶ Tested and tried
- ▶ But no interface
 - ▶ Thus no compiler checks when you call it
 - ▶ And rewriting a working code in modern language is soooo dangerous...

- ▶ You are lucky, and inherit a 4000 lines of code library, coming from the dark ages
 - ▶ Tested and tried
- ▶ But no interface
 - ▶ Thus no compiler checks when you call it
 - ▶ And rewriting a working code in modern language is soooo dangerous...
- ▶ Modules come to rescue
 - ▶ They don't need to include the actual code
 - ▶ But they can publish an interface for code which is elsewhere
 - ▶ And then you can use the module in calling program units

```
module dspmod

  implicit none

  interface
    function theta(x)
      real :: theta
      real, intent(in) :: x
    end function theta
  end interface

  interface
    function sinc(x)
      real :: sinc
      real, intent(in) :: x
    end function sinc
  end interface

  interface
    function rect(t, tau)
      real :: rect
      real, intent(in) :: t, tau
    end function rect
  end interface

end module dspmod

► Euclid's Algorithm

1. Take two integers a and b
 2. Let $r \leftarrow a \bmod b$
 3. Let $a \leftarrow b$
 4. Let $b \leftarrow r$
 5. If b is not zero, go back to step 2
 6. a is the GCD
-
- Let's implement it and learn some more Fortran

```
module number_theory
  implicit none
  contains
  function gcd(a, b) ! Greatest Common Divisor
    integer :: gcd
    integer, intent(in) :: a, b
    integer :: gb, t

    gcd = a
    gb = b

    do
      t = mod(gcd,gb)
      gcd = gb
      if (t == 0) exit
      gb = t
    end do
  end function gcd

  function lcm(a, b) ! Least Common Multiple
    integer :: lcm
    integer, intent(in) :: a, b

    lcm = a*b/gcd(a,b)
  end function lcm
end module number_theory
```

```
module number_theory
  implicit none
  contains
  function gcd(a, b) ! Greatest Common Divisor
    integer :: gcd
    integer, intent(in) :: a, b
    integer :: gb, t

    gcd = a
    gb = b

    do
      t = mod(gcd,gb)
      gcd = gb
      if (t == 0) exit
      gb = t
    end do
  end function gcd

  function lcm(a, b) ! Least Common Multiple
    integer :: lcm
    integer, intent(in) :: a, b

    lcm = a*b/gcd(a,b)
  end function lcm
end module number_theory
```

The Integer Type

- ▶ As we said, **integer** means that a value is an integer
 - ▶ Only integer values, positive, negative or zero
 - ▶ On most platforms, **integer** means a 32 bits value, ranging from -2^{31} to $2^{31} - 1$

The Integer Type

- ▶ As we said, **integer** means that a value is an integer
 - ▶ Only integer values, positive, negative or zero
 - ▶ On most platforms, **integer** means a 32 bits value, ranging from -2^{31} to $2^{31} - 1$
- ▶ Want to know the actual size?
 - ▶ The standard is absolutely generic on this

The Integer Type

- ▶ As we said, **integer** means that a value is an integer
 - ▶ Only integer values, positive, negative or zero
 - ▶ On most platforms, **integer** means a 32 bits value, ranging from -2^{31} to $2^{31} - 1$
- ▶ Want to know the actual size?
 - ▶ The standard is absolutely generic on this
 - ▶ But we'll tell you a secret...

- ▶ As we said, **integer** means that a value is an integer
 - ▶ Only integer values, positive, negative or zero
 - ▶ On most platforms, **integer** means a 32 bits value, ranging from -2^{31} to $2^{31} - 1$
- ▶ Want to know the actual size?
 - ▶ The standard is absolutely generic on this
 - ▶ But we'll tell you a secret...
 - ▶ ...on all platforms we know of, the intrinsic function **kind()** will return the size in bytes of any integer expression you'll pass as an argument

- ▶ As we said, **integer** means that a value is an integer

 - ▶ But we'll tell you a secret...
 - ▶ ...on all platforms we know of, the intrinsic function **kind()** will return the size in bytes of any integer expression you'll pass as an argument
 - ▶ Try with **kind(0)**, to know the size of a normal **integer**
 - ▶ And works for real values too, or values of any type, for that matter
 - ▶ More on this later

- ▶ As we said, **integer** means that a value is an integer
 - ▶ Only integer values, positive, negative or zero
 - ▶ On most platforms, **integer** means a 32 bits value, ranging from -2^{31} to $2^{31} - 1$
- ▶ Want to know the actual size?
 - ▶ The standard is absolutely generic on this
 - ▶ But we'll tell you a secret...
 - ▶ ...on all platforms we know of, the intrinsic function **kind()** will return the size in bytes of any integer expression you'll pass as an argument
 - ▶ Try with **kind(0)**, to know the size of a normal **integer**
 - ▶ And works for real values too, or values of any type, for that matter
 - ▶ More on this later
- ▶ Want to know more?
 - ▶ Intrinsic function **huge(0)** returns the greatest positive value an **integer** can assume
 - ▶ Again, we'll be back at this

```

Iterating with `do . . . end do`

► `do`

block of statements

`end do`

1. Executes again and again the *block of statements*
2. And does this forever...
3. ... unless `exit` is executed, forcing execution to proceed at code following `end do`

► `do`

block of statements

`end do`

1. Executes again and again the *block of statements*
2. And does this forever...
3. ... unless `exit` is executed, forcing execution to proceed at code following `end do`

► In this specific example:

Iterating with `do . . . end do`

▶ `do`

block of statements

`end do`

1. Executes again and again the *block of statements*
2. And does this forever...
3. ... unless `exit` is executed, forcing execution to proceed at code following `end do`

▶ In this specific example:

- ▶ the code following `end do` is the end of the function
- ▶ thus, we could use `return` instead of `exit`, which is legal,
- ▶ but generally regarded bad practice

▶ **do**

block of statements

end do

1. Executes again and again the *block of statements*
2. And does this forever...
3. ... unless **exit** is executed, forcing execution to proceed at code following **end do**

▶ In this specific example:

- ▶ the code following **end do** is the end of the function
- ▶ thus, we could use **return** instead of **exit**, which is legal,
- ▶ but generally regarded bad practice

▶ Best practice: do not bail out of a function from inside a loop, particularly a long one

- ▶ And let's add support for a wider integer range
- ▶ Wait!
 - ▶ Now we have to remember to call the right function, depending on the integer kind
 - ▶ But this is not Fortran style: we didn't have to change the call to intrinsic **abs ()**, it's name is generic
 - ▶ Can we do better?
- ▶ Yes, we can do better!
 - ▶ **interface** blocks come to rescue
 - ▶ Beware: specific functions under a same generic interface must differ in type of at least one argument
 - ▶ and **module procedure** spares us typing and inconsistencies
 - ▶ and **private** allows us to hide implementation details
- ▶ Best practices for robustness:
 - ▶ write generic procedures, whenever possible
 - ▶ hide implementation details, whenever possible

```
FUNCTION GCD18(A, B)
  INTEGER*8 GCD18, A, B
  INTEGER*8 GB, T

  GCD18 = A
  GB = B

1   T = MOD(GCD18,GB)
   GCD18 = GB
   IF (T .EQ. 0) GO TO 2
   GB = T
   GO TO 1

2   CONTINUE
END

FUNCTION LCM18(A, B)
  INTEGER*8 LCM18, A, B
  INTEGER*8 GCD18
  EXTERNAL GCD18

  LCM18 = A*B/GCD18(A,B)
END
```

- ▶ No structured endless loops
 - ▶ Labels and `GO TO`s were used instead
- ▶ **CONTINUE** was a no-op
 - ▶ Used to mark destination of jumps
 - ▶ No comment
- ▶ **INTEGER*8** was used to declare an 8 bytes integer variable
 - ▶ Absolutely non standard
 - ▶ As are **INTEGER*1**, **INTEGER*2**, **INTEGER*4**, **REAL*4**, **REAL*8**, **COMPLEX*8**, **COMPLEX*16**
- ▶ Many dialects
 - ▶ Many proprietary extensions used to be developed
 - ▶ And then copied among vendors for compatibility reasons
 - ▶ Many extensions were eventually standardized
 - ▶ But not all of them!
 - ▶ They still lurk around, and can be tempting: resist!

- ▶ There are many integer types
 - ▶ With implementation dependent ranges
 - ▶ Selectable by kind type parameters
 - ▶ Whose limits can be devised using **huge ()** or **range ()**
- ▶ Library functions have generic names, good for most types
- ▶ And you can write your own generic interfaces
- ▶ Behavior on integer overflow is implementation defined
 - ▶ Some control is possible using parentheses
- ▶ Blocks of statements can be iterated forever...
 - ▶ ... and **exit** gets off the roundabout
- ▶ Logical conditions can be combined using **.or.** and **.and.** operators

- ▶ Do not rely on type sizes, they are implementation dependent
- ▶ Do not leave a function from inside a loop
- ▶ Think of intermediate results in expressions: they can overflow or underflow
- ▶ Be consistent with Fortran approach
 - ▶ E.g. writing generic interfaces
 - ▶ Even if it costs more work
 - ▶ Even if it costs learning more Fortran
 - ▶ Once again, you can do it in steps
 - ▶ You'll appreciate it in the future
- ▶ Hide implementation details as much as possible
 - ▶ You'll never regret
- ▶ Resist the temptation of old Fortran or non standard extensions
 - ▶ Will pay back in the future

Creating an executable from source files is in general a three phase process:

- ▶ pre-processing:
 - ▶ each source file is read by the pre-processor
 - ▶ substitute (**#define**) MACROS
 - ▶ insert code by **#include** statements
 - ▶ insert or delete code evaluating **#ifdef**, **#if** ...
- ▶ compiling:
 - ▶ each source file is translated into an object code file
 - ▶ an object code file is an organised collection of symbols, referring to variables and functions defined or used in the source file
- ▶ linking:
 - ▶ object files should be combined together to build a single executable program
 - ▶ every symbol should be resolved
 - ▶ symbols can be defined in your object files
 - ▶ or available in other object code (external libraries)

- ▶ When you give the command:

```
user@cineca$> gfortran dsp.f90 dsp_test.f90
```

- ▶ When you give the command:

```
user@cineca$> gfortran dsp.f90 dsp_test.f90
```

- ▶ It's like going through three steps

- ▶ When you give the command:

```
user@cineca$> gfortran dsp.f90 dsp_test.f90
```

- ▶ It's like going through three steps
- ▶ Pre-processing

```
user@cineca$> gfortran -E -cpp dsp.f90  
user@cineca$> gfortran -E -cpp dsp_test.f90
```

- ▶ **-E -cpp** option, tells **gfortran** to stop after pre-process
- ▶ Simply calls **cpp** (automatically invoked if the file extension is **F90**)
- ▶ Output sent to standard output

- ▶ When you give the command:

```
user@cineca$> gfortran dsp.f90 dsp_test.f90
```

- ▶ It's like going through three steps
- ▶ Pre-processing

```
user@cineca$> gfortran -E -cpp dsp.f90  
user@cineca$> gfortran -E -cpp dsp_test.f90
```

- ▶ **-E -cpp** option, tells **gfortran** to stop after pre-process
- ▶ Simply calls **cpp** (automatically invoked if the file extension is **F90**)
- ▶ Output sent to standard output
- ▶ Compiling sources

```
user@cineca$> gfortran -c dsp.f90  
user@cineca$> gfortran -c dsp_test.f90
```

- ▶ **-c** option tells **gfortran** to only compile the source
- ▶ An object file **.o** is produced from each source file

- ▶ Linking object files together

```
user@cineca$> gfortran dsp.o dsp_test.o
```

- ▶ To resolve symbols defined in external libraries, specify:
 - ▶ which libraries to use (`-l` option)
 - ▶ in which directories they are (`-L` option)
- ▶ How to link the library `libdsp.a` in `/mypath`

```
user@cineca$> gfortran file1.o file2.o -L/mypath -ldsp
```

- ▶ How to create and link the DSP library:

```
user@cineca$> gfortran -c dsp.f90  
ar curv libdsp.a dsp.o  
ranlib libdsp.a  
gfortran test_dsp.f90 -L. -ldsp
```

- ▶ `ar` create the archive `libdsp.a` containing `dsp.o`
 - ▶ `ranlib` generate index to archive
- ▶ To include file like `.mod`, specify
 - ▶ in which directories they are (`-I` option)

More Fortran Basics

Integer Types and Iterating

More on Compiling and Linking

Homeworks

- ▶ Write a program that reads an integer value `limit` and prints the first `limit` prime numbers
 - ▶ Use the GCD function to identify those numbers
 - ▶ After testing the basic version, handle negative `limit` values: print an error message and attempt to read the value again

- ▶ Write a module containing a function that takes an integer n as input, and returns the n -th element of the Fibonacci series f_n
- ▶ Hint:
 - ▶ $F_0 = 0$
 - ▶ $F_1 = 1$
 - ▶ $F_n = F_{n-1} + F_{n-2}$
- ▶ Write a main program to test your function
 - ▶ Read n from standard input
 - ▶ Try with $n=2, 10, 40, 46, 48, \dots$
 - ▶ What's the greatest $n := \max n$, for which f_n is representable by a default integer? (**huge** can help to find it out)
 - ▶ Use this information to handle too large values of n in your function:
 - ▶ If $n > \max n$ print an error message and return -1

Part II

A Fortran Survey 2

Passing functions as arguments of procedures. Conditional and numerical loops. Managing the precision, conversions, overflow, underflow, Inf e NaN. Expressions and subexpressions with mixed types. Types, operators and logical expressions. Type character and intrinsic functions for strings. Subroutine. Array. Default constructor for arrays and implicit loops. Assumed-shape array and automatic object. Expressions with arrays and conformity.

More Flow Control

Fortran Intrinsic Types, Variables and Math

Arrays

The code in this section is meant for didactical purposes only.

It is deliberately naive: focus is on language aspects, not on precision or accuracy.

As a consequence, it is prone to numerical problems.

More Flow Control
Numerical Integration

Fortran Intrinsic Types, Variables and Math

Arrays

- ▶ Let's use the trapezoidal rule to estimate $\int_a^b f(x) dx$
- ▶ Dividing the interval $[a, b]$ into n equal sized slices, it boils down to:

$$\int_a^b f(x) dx \approx \frac{b-a}{n} \left(\frac{1}{2}f(a) + \frac{1}{2}f(b) + \sum_{k=1}^{n-1} f\left(a + k\frac{b-a}{n}\right) \right)$$

- ▶ And to make it more juicy, let's make a succession of estimates, doubling n each time, until the estimate seems stable

```

- More Intrinsic Types

Arrays

- ▶ Computing == manipulating data and calculating results
 - ▶ Data are manipulated using internal, binary formats
 - ▶ Data are kept in memory locations and CPU registers
- ▶ Fortran doesn't make assumptions on internal data representations
 - ▶ And tries to abstract
 - ▶ Most CPU are similar but all have peculiarities
 - ▶ Some details depend on the specific executing (a.k.a. target) hardware architecture and software implementation
 - ▶ Fortran provides facilities to translate between internal formats and human readable ones
- ▶ Fortran allows programmers to:
 - ▶ think in terms of data types and named containers
 - ▶ disregard details on actual memory locations and data movements

Fortran is a Strongly Typed Language

- ▶ Each literal constant has a type
 - ▶ Dictates internal representation of the data value
- ▶ Each variable has a type
 - ▶ Dictates content internal representation and amount of memory
 - ▶ Type must be specified in a declaration before use
 - ▶ Unless you are so naive to rely on implicit declaration
- ▶ Each expression has a type
 - ▶ And subexpressions have too
 - ▶ Depends on operators and their arguments
- ▶ Each function has a type
 - ▶ That is the type of the returned value
 - ▶ Specified in function interface
- ▶ Procedure arguments have types
 - ▶ i.e. type of arguments to be passed in calls
 - ▶ Specified in procedure interface
 - ▶ If the compiler doesn't know the interface, it will blindly pass whatever you provide

More Flow Control

Fortran Intrinsic Types, Variables and Math

Integer Types

Floating Types

Expressions

Arithmetic Conversions

More Intrinsic Types

Arrays

Integer Types (as on most CPUs)

Type	Sign	Usual huge ()	Usual Width (bits)	Usual Size (bytes)
<code>integer(selected_int_kind(2))</code>	+/-	127	8	1
<code>integer(selected_int_kind(5))</code>	+/-	32767	16	2
<code>integer</code> <code>integer(kind(0))</code> <code>integer(selected_int_kind(9))</code>	+/-	2147483647	32	4
<code>integer(selected_int_kind(18))</code>	+/-	9223372036854775807	64	8

- ▶ `selected_int_kind(n)` returns the least type able to host 10^n
- ▶ `selected_int_kind(n)` returns -1 if no suitable type is available
- ▶ New platform/compiler? Always check maximum headroom with `huge ()` or `range ()`
- ▶ As we said, on most platforms `kind ()` returns the byte size, but it's not standard

Integer Literal Constants

- ▶ Integer literal constants have kinds too

Integer Literal Constants

- ▶ Integer literal constants have kinds too
- ▶ By default, `kind(0)`

- ▶ Integer literal constants have kinds too
- ▶ By default, `kind(0)`
- ▶ Unless you specify it

- ▶ In a non portable way:

`-123456_8`

- ▶ Or in a portable way:

```
integer, parameter :: i8=selected_int_kind(18)  
-123456_i8
```

- ▶ Integer literal constants have kinds too
- ▶ By default, `kind(0)`
- ▶ Unless you specify it
 - ▶ In a non portable way:
`-123456_8`
 - ▶ Or in a portable way:

```
integer, parameter :: i8=selected_int_kind(18)  
-123456_i8
```
- ▶ Rule of thumb:
 - ▶ write the number as is, if it is in default integer kind range
 - ▶ otherwise, specify kind

- ▶ Integer literal constants have kinds too
- ▶ By default, `kind(0)`
- ▶ Unless you specify it
 - ▶ In a non portable way:
`-123456_8`
 - ▶ Or in a portable way:
`integer, parameter :: i8=selected_int_kind(18)`
`-123456_i8`
- ▶ Rule of thumb:
 - ▶ write the number as is, if it is in default integer kind range
 - ▶ otherwise, specify kind
- ▶ Remember:
 - ▶ do not write `spokes = bicycles*2*36`
 - ▶ `integer, parameter :: SpokesPerWheel = 36`
 - ▶ code will be more readable, and you'll be ready for easy changes

Function	Returns
abs (i)	$ i $
sign (i, j)	$ i $ if $j \geq 0$, $- i $ otherwise
dim (i, j)	if $i > j$ returns $i - j$ else returns 0
mod (i, j)	Remainder function $i - \text{int}(i/j) \times j$
modulo (i, j)	Modulo function $i - \text{floor}(i/j) \times j$
min (i, j[, ...])	$\min\{i, j[, \dots]\}$
max (i, j[, ...])	$\max\{i, j[, \dots]\}$

- ▶ Use like: **a = abs (b+i) + c**
- ▶ More functions are available to manipulate values
 - ▶ E.g. for bit manipulations on binary computers
 - ▶ We'll not cover them in this course, you can learn more about if you need to
- ▶ They can be found under different names (e.g. **iabs ()**): these are relics from the past

More Flow Control

Fortran Intrinsic Types, Variables and Math

Integer Types

Floating Types

Expressions

Arithmetic Conversions

More Intrinsic Types

Arrays

Floating Types (as on most CPUs)

Type	Usual huge ()	Usual Width (bits)	Usual Size (bytes)
<pre>real real(kind(0.0)) real(selected_real_kind(6))</pre>	3.40282347e38	32	4
<pre>double precision real(kind(0.0d0)) real(selected_real_kind(15)) real(selected_real_kind(18))</pre>	1.79769313486231573e308	64	8
<pre>real(selected_real_kind(18))</pre>	> 1.2e4932	80 or 128	10 or 16
<pre>complex complex(kind(0.0)) complex(selected_real_kind(6))</pre>	NA	NA	8
<pre>complex(kind(0.0d0)) complex(selected_real_kind(15)) complex(selected_real_kind(18))</pre>	NA	NA	16
<pre>complex(selected_real_kind(18))</pre>	NA	NA	20 or 32

- ▶ In practice, always in IEEE Standard binary format, but not a Standard requirement
- ▶ `selected_real_kind()` gets number of significant decimal digits, plus a second optional argument for exponent range, returns negative result if no suitable type is available
- ▶ `tiny()` returns smallest positive value
- ▶ New platform/compiler? Always check maximum headroom with `huge()` or `range()`

real Literal Constants

- ▶ Need something to distinguish them from integers
 - ▶ Decimal notation: **1.0**, **-17.**, **.125**, **0.22**
 - ▶ Exponential decimal notation: **2e19** (2×10^{19}), **-123.4e9** (-1.234×10^{11}), **.72e-6** (7.2×10^{-7})

real Literal Constants

- ▶ Need something to distinguish them from integers
 - ▶ Decimal notation: `1.0`, `-17.`, `.125`, `0.22`
 - ▶ Exponential decimal notation: `2e19` (2×10^{19}), `-123.4e9` (-1.234×10^{11}), `.72e-6` (7.2×10^{-7})
- ▶ By default, `kind(0.0)`

- ▶ Need something to distinguish them from integers
 - ▶ Decimal notation: `1.0`, `-17.`, `.125`, `0.22`
 - ▶ Exponential decimal notation: `2e19` (2×10^{19}), `-123.4e9` (-1.234×10^{11}), `.72e-6` (7.2×10^{-7})
- ▶ By default, `kind(0.0)`
- ▶ Unless you specify it
 - ▶ For double precision only:
`-1.23456d5`
 - ▶ For all kinds:

```
integer, parameter :: r8=selected_real_kind(15)
-123456.0_r8
```

- ▶ Need something to distinguish them from integers
 - ▶ Decimal notation: `1.0`, `-17.`, `.125`, `0.22`
 - ▶ Exponential decimal notation: `2e19` (2×10^{19}), `-123.4e9` (-1.234×10^{11}), `.72e-6` (7.2×10^{-7})

- ▶ By default, `kind(0.0)`

- ▶ Unless you specify it

- ▶ For double precision only:

`-1.23456d5`

- ▶ For all kinds:

```
integer, parameter :: r8=selected_real_kind(15)  
-123456.0_r8
```

- ▶ Remember:

- ▶ do not write `charge = protons*1.602176487E-19`
 - ▶ `real,parameter::UnitCharge=1.602176487E-19`
 - ▶ it will come handier when more precise measurements will be available

Function	Returns
abs (x)	$ x $
sign (x, y)	$ x $ if $y \geq 0$, $- x $ otherwise
dim (x, y)	if $x > y$ returns $x - y$ else returns 0
mod (x, y)	Remainder function $x - \text{int}(x/y) \times y$
modulo (x, y)	Modulo function $x - \text{floor}(x/y) \times y$
aint (x)², int (x)^{1,2}	if $x > 0$ returns $\lfloor x \rfloor$ else returns $\lceil x \rceil$
anint (x)², nint (x)^{1,2}	nearest integer to x
floor (x)^{1,2}, ceiling (x)^{1,2}	$\lfloor x \rfloor$, $\lceil x \rceil$
fraction (x)	fractional part of x
nearest (x, s)	next representable value to x , in direction given by the sign of s
spacing (x)	absolute spacing of numbers near x
max (x, y[, ...])	$\max\{x, y[, \dots]\}$
min (x, y[, ...])	$\min\{x, y[, \dots]\}$
1. Result is of integer type 2. Accept an optional argument for kind type of the result	

- ▶ They can be found under different names (e.g. **dabs ()**): these are relics from the past
- ▶ More functions are available to manipulate values
 - ▶ Mostly in the spirit of IEEE Floating Point Standard
 - ▶ We'll not cover them in this course, but encourage you to learn more about

Functions	Compute
sqrt (x)	\sqrt{x}
sin (x), cos (x), tan (x), asin (x), acos (x), atan (x)	Trigonometric functions
atan2 (x, y)	Arc tangent in $(-\pi, \pi]$
exp (x), log (x), log10 (x)	e^x , $\log_e x, \log_{10} x$
sinh (x), cosh (x), tanh (x)	Hyperbolic functions

- ▶ Again, they can be found under different names (e.g. **dcos ()**): these are relics from the past

Functions	Compute
abs (z),	$ z $,
aimag (z)	imaginary part of z ,
real (z) ¹	real part of z
cmplx (x , y) ¹	converts from real to complex
conj (z)	Complex conjugate of z
sqrt (z)	\sqrt{z}
sin (z), cos (z)	sine and cosine
exp (z), log (z)	e^z , $\log_e z$
1. Accept an optional argument for kind type of the result	

- ▶ Once again, they can be found under different names (e.g. **cabs** ()): again, these are relics from the past

- ▶ The intrinsic function **precision (x)** for real or complex **x** returns the number of significant decimal digits.
- ▶ Write a **module** which defines the **kind** constant for single, double and quadruple real precision

- ▶ The intrinsic function **precision (x)** for real or complex **x** returns the number of significant decimal digits.
- ▶ Write a **module** which defines the **kind** constant for single, double and quadruple real precision

- ▶ The intrinsic function **precision (x)** for real or complex **x** returns the number of significant decimal digits.
- ▶ Write a **module** which defines the **kind** constant for single, double and quadruple real precision
- ▶ To gain confidence: write a small program to print out **range** and **huge** values for these kinds

- ▶ The intrinsic function **precision (x)** for real or complex **x** returns the number of significant decimal digits.
- ▶ Write a **module** which defines the **kind** constant for single, double and quadruple real precision
- ▶ To gain confidence: write a small program to print out **range** and **huge** values for these kinds
- ▶ Something going wrong?

- ▶ The intrinsic function **precision (x)** for real or complex **x** returns the number of significant decimal digits.
- ▶ Write a **module** which defines the **kind** constant for single, double and quadruple real precision
- ▶ To gain confidence: write a small program to print out **range** and **huge** values for these kinds
- ▶ Something going wrong?
- ▶ GNU Fortran compiler, up to release 4.5, lacks support for the quad-precision
- ▶ If you are using Linux, load the most recent GNU compiler version and try again:
module load gnu

- ▶ Use the `real_kinds` module to rewrite `dsp` module functions to support both single and double precision
- ▶ And make all of them generic procedures
- ▶ Modify your test program to see exercise the new `dsp` module

a = b*2 + 1_i8
multiplication will overflow too

- ▶ For the assignment statement:
 - ▶ if variable and expression have the same type, fine
 - ▶ otherwise, right operand is converted to left operand type
 - ▶ if the value cannot be represented in the destination type, it's an overflow, and you are on your own

- ▶ We said: in order of precedence and associativity
 - ▶ if **a** is a 64 bits wide integer variable, and **b** is a 32 bits wide integer variable and contains value **huge (0)**, in:
a = b*2
multiplication will overflow
 - ▶ and in (**i8** as in a previous example):
a = b*2 + 1_i8
multiplication will overflow too
 - ▶ while:
a = b*2_i8 + 1
is OK

- ▶ Think of mixing floating and integer types

Subtle Type Conversion Traps

- ▶ Think of mixing floating and integer types
- ▶ Floating types have wider dynamic range than integer ones

Subtle Type Conversion Traps

- ▶ Think of mixing floating and integer types
- ▶ Floating types have wider dynamic range than integer ones
- ▶ But not necessarily more precision

- ▶ Think of mixing floating and integer types
- ▶ Floating types have wider dynamic range than integer ones
- ▶ But not necessarily more precision
- ▶ A 32 bits `real` has fewer digits of precision than a 32 bits `integer`

- ▶ Think of mixing floating and integer types
- ▶ Floating types have wider dynamic range than integer ones
- ▶ But not necessarily more precision
- ▶ A 32 bits `real` has fewer digits of precision than a 32 bits `integer`
- ▶ And a 64 bits `real` has fewer digits of precision than a 64 bits `integer`

- ▶ Think of mixing floating and integer types
- ▶ Floating types have wider dynamic range than integer ones
- ▶ But not necessarily more precision
- ▶ A 32 bits `real` has fewer digits of precision than a 32 bits `integer`
- ▶ And a 64 bits `real` has fewer digits of precision than a 64 bits `integer`
- ▶ The result of a conversion could actually be smaller than expected!

- ▶ Do not blindly rely on implementation dependent chance!

- ▶ Do not blindly rely on implementation dependent chance!
- ▶ Use explicit type conversion functions:
 - ▶ `int(x[, kind])`
 - ▶ `real(x[, kind])`
 - ▶ `cmplx(x[, y][, kind])`

Fortran Intrinsic Types, Variables and Math

Integer Types

Floating Types

Expressions

Arithmetic Conversions

More Intrinsic Types

Arrays

- ▶ A type good at reasoning
 - ▶ May have `.false.` or `.true.` value
 - ▶ Kind only affects size in memory

- ▶ A type good at reasoning
 - ▶ May have `.false.` or `.true.` value
 - ▶ Kind only affects size in memory
- ▶ Arithmetic comparison operators return logical values
 - ▶ `==` (equal), `/=` (not equal), `>`, `<`, `>=`, `<=`
 - ▶ or, in ancient Fortran, `.eq.`, `.ne.`, `.gt.`, `.lt.`, `.ge.`, `.le.`

- ▶ A type good at reasoning
 - ▶ May have `.false.` or `.true.` value
 - ▶ Kind only affects size in memory
- ▶ Arithmetic comparison operators return logical values
 - ▶ `==` (equal), `/=` (not equal), `>`, `<`, `>=`, `<=`
 - ▶ or, in ancient Fortran, `.eq.`, `.ne.`, `.gt.`, `.lt.`, `.ge.`, `.le.`
- ▶ Logical expressions
 - ▶ `.not.` is unary NOT, `.and.` and `.or.` are binary AND and OR respectively, `.eqv.` is logical equivalence (`.true.` if operands both `.true.` or both `.false.`)
 - ▶ `.not. a .and. b .or. a .and. .not. b`
means
`((.not.a) .and. b) .or. (a .and. (.not.b))`
 - ▶ In doubt, add parentheses, but be sober

- ▶ Logical friends from `ieee_arithmetic` module (simply use it)
 - ▶ `ieee_is_finite(x): .true.` if argument value is finite
 - ▶ `ieee_is_nan(x): .true.` if argument value is NaN
 - ▶ `ieee_unordered(x, y): .true.` if at least one among `x` and `y` is NaN

- ▶ Logical friends from `ieee_arithmetic` module (simply use it)
 - ▶ `ieee_is_finite(x): .true.` if argument value is finite
 - ▶ `ieee_is_nan(x): .true.` if argument value is NaN
 - ▶ `ieee_unordered(x, y): .true.` if at least one among x and y is NaN
- ▶ As usual, order of subexpressions evaluation is implementation dependent

- ▶ Logical friends from `ieee_arithmetic` module (simply use it)
 - ▶ `ieee_is_finite(x): .true.` if argument value is finite
 - ▶ `ieee_is_nan(x): .true.` if argument value is NaN
 - ▶ `ieee_unordered(x, y): .true.` if at least one among `x` and `y` is NaN
- ▶ As usual, order of subexpressions evaluation is implementation dependent
- ▶ But it's worse:
 - ▶ if `test()` is a function returning a logical type value
 - ▶ and `a` is `.true.`
 - ▶ and `b` is `.false.`
 - ▶ implementation is free (but not forced!) to not call `test()` at all in `a.or.test(x)` and `b.and.test(x)`
 - ▶ Again, do not rely on expressions side effects

- ▶ Fortran is not that good at manipulating text
- ▶ But it has some **character**:
 - ▶ **character** :: **c** defines a variable holding a single character, like ' **f** '
 - ▶ **character(len=80)** :: **s1, s2, s3** defines three variables holding strings of up to 80 characters, like ' **Fortran 2003** '
- ▶ There are character expressions, like:
 - ▶ **s3(1:40) = s1(1:20)//s2(21:40)**
which assigns to first half of **s3** the first quarter of **s1** and second quarter of **s2**
- ▶ On assignment of a character expression to a longer variable, blank filling will take place
- ▶ On assignment of a character expression to a shorter variable, truncation will happen

Function	Returns
<code>len(s)</code>	string length
<code>len_trim(s)</code>	string length with trailing blanks ignored
<code>trim(s)</code>	string with trailing blanks removed
<code>repeat(s, n)</code>	string made of <code>n</code> copies of <code>s</code>
<code>adjustl(s)</code>	move leading blanks to trailing position
<code>adjustr(s)</code>	move trailing blanks to leading position
<code>lge(s1, s2),</code> <code>lgt(s1, s2),</code> <code>lle(s1, s2),</code> <code>llt(s1, s2)</code>	string comparisons
<code>index(s, subs)</code>	starting position of <code>subs</code> in <code>s</code> , 0 if not found
<code>scan(s, set)</code>	first position in <code>s</code> of a character matching <code>set</code> , 0 if none found
<code>verify(s, set)</code>	first position in <code>s</code> of a character not matching <code>set</code> , 0 if all match
<code>achar(i)</code>	character with ASCII code <code>i</code>
<code>iachar(c)</code>	ASCII code of character <code>c</code>

► Our advice:

- For most practical purposes, use I/O statements to manipulate strings as internal files (more on this later)
- If you are really serious about textual data, learn more
- Or switch to a different language

 - ▶ **work(1:n)** selects the successive **n** elements
 - ▶ **work(n+1:n+k)** selects...
- ▶ Arrays and array sections are assigned to by = in a natural manner (more on this later)

Same Smoothing in a Different Idiom

```
module smoothing
  implicit none
  contains

  subroutine smoothinplace(v, k)
    implicit none
    real,intent(inout) :: v(:)
    integer,intent(in)  :: k
    real                :: work(-k+1:size(v)+k)
    integer :: i, j, l, n

    n=size(v)
    l = 2*k + 1
    work(1:n) = v
    work(-k+1:0) = v(n-k+1:n)
    work(n+1:n+k) = v(1:k)

    do j=1, k
      v = v + work(1-j:n-j) + work(1+j:n+j)
    end do
    v = v/l

  end subroutine smoothinplace
end module smoothing
```

- ▶ Arrays and array sections may be
 - ▶ referenced and used in expressions
 - ▶ passed as arguments to procedures

```
do j=1, k
  v = v + work(1-j:n-j) + work(1+j:n+j)
end do
```

- ▶ Without array expressions, this code would look like:

```
do j=1, k
  do i=1, n
    v(i) = v(i) + work(i-j) + work(i+j)
  end do
end do
```

- ▶ In an array expression, result must not depend in any way on the order of evaluation of elements
- ▶ You should think of array expressions as if all elements were computed at the same time

- ▶ The size of a one-dimensional array is its *shape*
- ▶ Arithmetic operators act on arrays element by element
- ▶ Binary operators combine pairs of corresponding elements from the operands
- ▶ With binary operators and assignments, you must use *conformable*, i.e. identically shaped, arrays
- ▶ Except for scalar values (not variables!), that match any shape, as if they were replicated

```
real, dimension(4) :: u, v, w
real :: t(1), s
t = s ! it's right
s = t ! it's wrong
w = (u-v)**2 ! it's right
w = s*u+v+2.3 ! it's OK
w = u+v(1:2) ! it's wrong
```

- ▶ By the way, **dimension** attribute lets you specify bounds and dimensions for a list of identical arrays

- ▶ Intrinsic subroutine **random_number (x)** returns pseudo-random numbers uniformly distributed in $[0, 1)$ interval
 - ▶ Takes an argument of type **real**, that can be either a scalar or an array
 - ▶ Returns one random number if **x** is a scalar
 - ▶ Returns an array of random numbers if **x** is an array

- ▶ Is **random_number ()** as uniform as advertised? Let's check...

Let's Build An Histogram

- ▶ Write a program that:
 1. reads an integer **niter** from standard input
 2. generates **niter** random numbers in interval $[0, 10)$
 3. builds an histogram and computes their average
 4. Prints out results

- ▶ To build the histogram:
 1. Initialize to 0s an array **hist** of 20 **integers** to hold the bin count, then, at each iteration:
 2. generate a random number
 3. find out the bin it belongs to (i.e. its index in the array **hist**)
 4. intrinsic **ceiling(x)** function helps: it returns $\lceil x \rceil$
 5. increment the corresponding array element and compute the percentages
 6. accumulate the sum of the random numbers to compute the average value

- ▶ A prime number is a natural number which has only two distinct natural divisors: 1 and itself
- ▶ Find all primes less than or equal to a given n by Eratosthenes' algorithm:
 1. create a list of consecutive integers from 2 to n
 2. let be $p \leftarrow 2$ the first prime
 3. strike from the list all multiples of p up to n
 4. let $p \leftarrow$ next number still in the list after p
 5. if $2p < n$, get back to step 3
 6. all remaining numbers in the list are primes

Try it now!

- ▶ A prime number is a natural number which has only two distinct natural divisors: 1 and itself
- ▶ Find all primes less than or equal to a given n by Eratosthenes' algorithm:
 1. create a list of consecutive integers from 2 to n
 2. let be $p \leftarrow 2$ the first prime
 3. strike from the list all multiples of p up to n
 4. let $p \leftarrow$ next number still in the list after p
 5. if $2p < n$, get back to step 3
 6. all remaining numbers in the list are primes

Try it now!

- ▶ How could you spare iterations?
- ▶ How could you spare memory?

Part III

Array Syntax and I/O

Multidimensional arrays, array-syntax, array-value function, temporary array, shape, data, reshape, constant array and elemental procedure. Coconstructs where, forall, array reduction. Advanced I/O: formats and descriptors, I/O to/from file, namelist, internal file, unformatted I/O, positioning instructions, stream access. Managing errors.

```
function avgk(v, k)

    implicit none

    real,intent(in) :: v(:, :)
    integer,intent(in) :: k
    real :: avgk(size(v,1)/k,size(v,2)/k)

    integer :: i, j, n, m

    n = (size(v,1)/k)*k
    m = (size(v,2)/k)*k

    avgk = 0.0

    do j=1, k
        do i=1, k
            avgk = avgk + v(i:n:k,j:m:k)
        end do
    end do

    avgk = avgk/k**2

end function avgk
```

```
function avgk(v, k)

    implicit none

    real,intent(in) :: v(:, :)
    integer,intent(in) :: k
    real :: avgk(size(v,1)/k,size(v,2)/k)

    integer :: i, j, n, m

    n = (size(v,1)/k)*k
    m = (size(v,2)/k)*k

    avgk = 0.0

    do j=1, k
        do i=1, k
            avgk = avgk + v(i:n:k,j:m:k)
        end do
    end do

    avgk = avgk/k**2

end function avgk
```

- ▶ Arrays may have up to 7 dimensions
- ▶ Lower bounds default to 1, but you can specify them as for one-dimensional arrays, like in `q(-k:k, 11:20)`
- ▶ Elements are referenced by a list of indices: `v(1, 1)`
- ▶ The sequence of extents of an array is termed its *shape*, e.g. if `a` is `real :: a(3, 2:5)` then:
 - ▶ `shape(a)` returns the array of extents `(/3, 4/)`
 - ▶ whereas `size(a)` returns `12`
- ▶ Multidimensional (i.e. `rank>1`) arrays and array sections may be involved in array expressions
- ▶ As in the case of rank 1 arrays, they must be conformable when needed:
`avgk(1:3, :) = avgk(5:9, :)` is wrong

- ▶ Some statements treat the elements of an array one by one in a special order, the *array element order*
 - ▶ obtained by counting most rapidly in the early dimensions
 - ▶ in the natural matrix representation this corresponds to storing the elements by column

a(1,1)	a(2,1)	a(3,1)	a(1,2)	a(2,2)	a(3,2)	a(1,3)	a(2,3)	a(3,3)	a(1,4)	a(2,4)	a(3,4)
--------	--------	--------	--------	--------	--------	--------	--------	--------	--------	--------	--------

- ▶ Most implementations actually store arrays in contiguous storage following the array element order
 - ▶ not required by the Standard, though
 - ▶ but crucial wrt performances, a typical optimization topic
- ▶ When dealing with complex data structures, the contiguity issue arises
 - ▶ Fortran 2008 adds the **contiguous** keyword to somehow address it

```
function avgk(v, k)

- ▶ Again, use compiler options for runtime bounds checking
- ▶ Again, very slow, only tolerable in debugging

► Good ol' style:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  do j=i+1,n
    b(j) = b(j) - A(j,i)*x(i)
  enddo
enddo
```

► Good ol' style:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  do j=i+1,n
    b(j) = b(j) - A(j,i)*x(i)
  enddo
enddo
```

► In modern idiom:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  b(i+1:n) = b(i+1:n) - A(i+1:n,i)*x(i)
enddo
```

- ▶ Good ol' style:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  do j=i+1,n
    b(j) = b(j) - A(j,i)*x(i)
  enddo
enddo
```

- ▶ In modern idiom:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  b(i+1:n) = b(i+1:n) - A(i+1:n,i)*x(i)
enddo
```

- ▶ What happens for $i==n$?

► Good ol' style:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  do j=i+1,n
    b(j) = b(j) - A(j,i)*x(i)
  enddo
enddo
```

► In modern idiom:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  b(i+1:n) = b(i+1:n) - A(i+1:n,i)*x(i)
enddo
```

► What happens for $i==n$?

- the array section $b(n+1:n)$ has zero size:
lower bound > upper bound

▶ Good ol' style:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  do j=i+1,n
    b(j) = b(j) - A(j,i)*x(i)
  enddo
enddo
```

▶ In modern idiom:

```
do i=1,n
  x(i) = b(i) / a(i,i)
  b(i+1:n) = b(i+1:n) - A(i+1:n,i)*x(i)
enddo
```

▶ What happens for $i==n$?

- ▶ the array section $b(n+1:n)$ has zero size:
lower bound > upper bound
- ▶ No operation is performed

Picking Up Array Elements

- ▶ `a(11:20)` specifies all elements from index 11 to index 20

Picking Up Array Elements

- ▶ `a(11:20)` specifies all elements from index 11 to index 20
- ▶ `a(11:20:2)` specifies all odd index elements from index 11 to index 19

Picking Up Array Elements

- ▶ **a (11:20)** specifies all elements from index 11 to index 20
- ▶ **a (11:20:2)** specifies all odd index elements from index 11 to index 19
- ▶ **a (19:10:-2)** specifies the same elements, but in reverse order

Picking Up Array Elements

- ▶ $\mathbf{a(11:20)}$ specifies all elements from index 11 to index 20
- ▶ $\mathbf{a(11:20:2)}$ specifies all odd index elements from index 11 to index 19
- ▶ $\mathbf{a(19:10:-2)}$ specifies the same elements, but in reverse order
- ▶ Thus $\mathbf{b = a(11:20)}$ takes elements 11th to 20th of \mathbf{a} and assigns them to \mathbf{b}

Picking Up Array Elements

- ▶ $\mathbf{a(11:20)}$ specifies all elements from index 11 to index 20
- ▶ $\mathbf{a(11:20:2)}$ specifies all odd index elements from index 11 to index 19
- ▶ $\mathbf{a(19:10:-2)}$ specifies the same elements, but in reverse order
- ▶ Thus $\mathbf{b = a(11:20)}$ takes elements 11th to 20th of \mathbf{a} and assigns them to \mathbf{b}
- ▶ And $\mathbf{b = a(20:11:-1)}$ does the same, but elements order is reversed

Picking Up Array Elements

- ▶ $\mathbf{a(11:20)}$ specifies all elements from index 11 to index 20
- ▶ $\mathbf{a(11:20:2)}$ specifies all odd index elements from index 11 to index 19
- ▶ $\mathbf{a(19:10:-2)}$ specifies the same elements, but in reverse order
- ▶ Thus $\mathbf{b = a(11:20)}$ takes elements 11th to 20th of \mathbf{a} and assigns them to \mathbf{b}
- ▶ And $\mathbf{b = a(20:11:-1)}$ does the same, but elements order is reversed
- ▶ Remember: \mathbf{b} and the right hand side expression must be conformable

Picking Up Array Elements

- ▶ $\mathbf{a(11:20)}$ specifies all elements from index 11 to index 20
- ▶ $\mathbf{a(11:20:2)}$ specifies all odd index elements from index 11 to index 19
- ▶ $\mathbf{a(19:10:-2)}$ specifies the same elements, but in reverse order
- ▶ Thus $\mathbf{b = a(11:20)}$ takes elements 11th to 20th of \mathbf{a} and assigns them to \mathbf{b}
- ▶ And $\mathbf{b = a(20:11:-1)}$ does the same, but elements order is reversed
- ▶ Remember: \mathbf{b} and the right hand side expression must be conformable
- ▶ Which in this case implies:

Picking Up Array Elements

- ▶ `a(11:20)` specifies all elements from index 11 to index 20
- ▶ `a(11:20:2)` specifies all odd index elements from index 11 to index 19
- ▶ `a(19:10:-2)` specifies the same elements, but in reverse order
- ▶ Thus `b = a(11:20)` takes elements 11th to 20th of `a` and assigns them to `b`
- ▶ And `b = a(20:11:-1)` does the same, but elements order is reversed
- ▶ Remember: `b` and the right hand side expression must be conformable
- ▶ Which in this case implies:
 - ▶ `size(shape(b))` returns 1

Picking Up Array Elements

- ▶ `a(11:20)` specifies all elements from index 11 to index 20
- ▶ `a(11:20:2)` specifies all odd index elements from index 11 to index 19
- ▶ `a(19:10:-2)` specifies the same elements, but in reverse order
- ▶ Thus `b = a(11:20)` takes elements 11th to 20th of `a` and assigns them to `b`
- ▶ And `b = a(20:11:-1)` does the same, but elements order is reversed
- ▶ Remember: `b` and the right hand side expression must be conformable
- ▶ Which in this case implies:
 - ▶ `size(shape(b))` returns 1
 - ▶ and `size(b)` returns 10

A Closer Look To Array Expressions

- ▶ In array assignment everything must happen 'as if' the r.h.s. expression is evaluated before assignment

A Closer Look To Array Expressions

- ▶ In array assignment everything must happen 'as if' the r.h.s. expression is evaluated before assignment
- ▶ To the benefit of performances, this is in many cases unnecessary

A Closer Look To Array Expressions

- ▶ In array assignment everything must happen ‘as if’ the r.h.s. expression is evaluated before assignment
- ▶ To the benefit of performances, this is in many cases unnecessary
- ▶ But difficult ones exist, like $\mathbf{x}(2:10) = \mathbf{x}(1:9)$

A Closer Look To Array Expressions

- ▶ In array assignment everything must happen 'as if' the r.h.s. expression is evaluated before assignment
- ▶ To the benefit of performances, this is in many cases unnecessary
- ▶ But difficult ones exist, like $\mathbf{x}(2:10) = \mathbf{x}(1:9)$
- ▶ In which $\mathbf{x}(2)$ may not be assigned $\mathbf{x}(1)$ value until the existing $\mathbf{x}(2)$ value is assigned to $\mathbf{x}(3)$, which itself...

- ▶ In array assignment everything must happen 'as if' the r.h.s. expression is evaluated before assignment
- ▶ To the benefit of performances, this is in many cases unnecessary
- ▶ But difficult ones exist, like $\mathbf{x}(2:10) = \mathbf{x}(1:9)$
- ▶ In which $\mathbf{x}(2)$ may not be assigned $\mathbf{x}(1)$ value until the existing $\mathbf{x}(2)$ value is assigned to $\mathbf{x}(3)$, which itself...
- ▶ A prudent (lazy?) compiler could add intermediate copies to temporary arrays

A Closer Look To Array Expressions

- ▶ In array assignment everything must happen 'as if' the r.h.s. expression is evaluated before assignment
- ▶ To the benefit of performances, this is in many cases unnecessary
- ▶ But difficult ones exist, like $\mathbf{x}(2:10) = \mathbf{x}(1:9)$

Input/Output

! Polynomial approximation of $J_0(x)$ for $-3 \leq x \leq 3$
 ! See Abramowitz&Stegun for details

```

function j0(x)
  implicit none
  real :: j0
  real, intent(in) :: x

  integer, parameter :: order = 6
  real, parameter, dimension(0:order) :: coeff = &
    (/ 1.0000000, &
      -2.2499997, &
       1.2656208, &
      -0.3163866, &
       0.0444479, &
      -0.0039444, &
       0.0002100 /)
  real :: xo3sq
  integer :: i

  xo3sq = (x/3.0)**2
  j0 = coeff(order)

  ! horner method
  do i=order, 1, -1
    j0 = j0*xo3sq + coeff(i-1)
  end do
end function j0
  
```

- ▶ **parameter** arrays are very good at storing tables of:
 - ▶ polynomial coefficients
 - ▶ physical measurements
 - ▶ function values at discrete points

- ▶ In the past, **data** statements were used:

```
data coeff /1.0,-2.2499997,1.2656208,-0.3163866, &  
          0.0444479,-0.0039444,0.0002100/
```

- ▶ **data** statements:
 - ▶ are very versatile
 - ▶ very difficult to decipher
 - ▶ and tend to float away from variable declaration

- ▶ Use initialization instead

Say it With `forall`s

- ▶ `forall` allows writing array assignments which cannot be expressed with array expressions:

```
forall(i = 1:n) a(i,i) = x(i)**2
```

Say it With `forall`s

- ▶ `forall` allows writing array assignments which cannot be expressed with array expressions:

```
forall(i = 1:n) a(i,i) = x(i)**2
```

- ▶ `forall` also accepts masks:

```
forall(i = 1:n, j = 1:n, y(i,j)/=0.) x(j,i) = 1.0/y(i,j)
```

Say it With `forall`s

- ▶ `forall` allows writing array assignments which cannot be expressed with array expressions:

```
forall(i = 1:n) a(i,i) = x(i)**2
```

- ▶ `forall` also accepts masks:

```
forall(i = 1:n, j = 1:n, y(i,j)/=0.) x(j,i) = 1.0/y(i,j)
```

- ▶ In its construct form, it looks like:

```
forall(i = 2:n-1, j = 2:n-1)  
  a(i,j) = a(i,j-1) + a(i,j+1) + a(i-1,j) + a(i+1,j)  
  b(i,j) = a(i,j)  
end forall
```

It works like array assignments:

Say it With `forall`s

- ▶ `forall` allows writing array assignments which cannot be expressed with array expressions:

```
forall(i = 1:n) a(i,i) = x(i)**2
```

- ▶ `forall` also accepts masks:

```
forall(i = 1:n, j = 1:n, y(i,j)/=0.) x(j,i) = 1.0/y(i,j)
```

- ▶ In its construct form, it looks like:

```
forall(i = 2:n-1, j = 2:n-1)  
  a(i,j) = a(i,j-1) + a(i,j+1) + a(i-1,j) + a(i+1,j)  
  b(i,j) = a(i,j)  
end forall
```

It works like array assignments:

- ▶ Unlike `do`, there is no ordering of iterations, and changes appear as they were deferred

Say it With `forall`s

- ▶ `forall` allows writing array assignments which cannot be expressed with array expressions:

```
forall(i = 1:n) a(i,i) = x(i)**2
```

- ▶ `forall` also accepts masks:

```
forall(i = 1:n, j = 1:n, y(i,j)/=0.) x(j,i) = 1.0/y(i,j)
```

- ▶ In its construct form, it looks like:

```
forall(i = 2:n-1, j = 2:n-1)  
  a(i,j) = a(i,j-1) + a(i,j+1) + a(i-1,j) + a(i+1,j)  
  b(i,j) = a(i,j)  
end forall
```

It works like array assignments:

- ▶ Unlike `do`, there is no ordering of iterations, and changes appear as they were deferred
- ▶ Thus, no conflicts between reads and writes to `a`

Say it With `forall`s

- ▶ `forall` allows writing array assignments which cannot be expressed with array expressions:

```
forall(i = 1:n) a(i,i) = x(i)**2
```

- ▶ `forall` also accepts masks:

- ▶ Assignment to `b(i,j)` takes place after that to `a(i,j)`
- ▶ Referenced procedures must be pure
- ▶ `forall` constructs can be nested and given a name

- Using `do` loops (dependencies! loop order is crucial)

```
do j=2,n-1
  do i=2,n-1
    T(i,j) = ( T(i-1,j) + T(i+1,j) + &
              T(i,j-1) + T(i,j+1) )/4.0
  enddo
enddo
```

- ▶ Using **do** loops (dependencies! loop order is crucial)

```

do j=2,n-1
  do i=2,n-1
    T(i,j) = ( T(i-1,j) + T(i+1,j) + &
              T(i,j-1) + T(i,j+1) )/4.0
  enddo
enddo
  
```

- ▶ Using array syntax (compiler enforces correct semantics)

```

T(2:n-1,2:n-1) = ( T(1:n-2,2:n-1) + T(3:n,2:n-1) &
                  + T(2:n-1,1:n-2) + T(2:n-1,3:n) )/4.0
  
```

- ▶ Using **do** loops (dependencies! loop order is crucial)

```
do j=2,n-1
  do i=2,n-1
    T(i,j) = ( T(i-1,j) + T(i+1,j) + &
              T(i,j-1) + T(i,j+1) )/4.0
  enddo
enddo
```

- ▶ Using array syntax (compiler enforces correct semantics)

```
T(2:n-1,2:n-1) = ( T(1:n-2,2:n-1) + T(3:n,2:n-1) &
                  + T(2:n-1,1:n-2) + T(2:n-1,3:n) )/4.0
```

- ▶ Using **forall** (ditto, but more readable)

```
forall (i=2:n-1, j=2:n-1)
  T(i,j) = ( T(i-1,j) + T(i+1,j) + &
            T(i,j-1) + T(i,j+1) )/4.0
end forall
```

```

integer, parameter :: maxn=768, maxm=939, R=3
real, parameter :: sd=10.0, sr=10.0
real, parameter :: sd22=2.0*sd**2, sr22=2.0*sr**2
integer :: i, j, m, n

...
do i=1,maxn      ! These two cannot be changed into forall
  do j=1,maxm    ! Why?
    z = 0.0      ! Because this happens at every iteration, it's a dependency!
    forall (m=max(1,i-R):min(maxn,i+R))
      forall (n=max(1,j-R):min(maxm,j+R))
        aw(m-i,n-j) = A(m,n)
        z(m-i,n-j) = exp(-(aw(m-i,n-j)-A(i,j))**2/sd22)*z0(m-i,n-j)
      end forall
    end forall
    B(i,j) = sum(z*aw)/sum(z)
  end do
end do
  
```

- ▶ Reductions squeeze an array to a scalar
 - ▶ **all** (*mask*) returns true if all the elements of mask are true
 - ▶ **any** (*mask*) returns true if any of the elements of mask are true
 - ▶ **count** (*mask*) returns the number of `.true.` elements in mask
 - ▶ **maxval** (*array*) returns the maximum value of array
 - ▶ **minval** (*array*) returns the minimum value of array
 - ▶ **sum** (*array*) returns the sum of the elements of array
 - ▶ **product** (*array*) returns the product of the elements of array
- ▶ Or to an array of rank reduced by one, if you specify an optional dimension to perform reduction along, like in `sum(a(:, :, :), dim=2)`

- ▶ More functions, good to know:
 - ▶ **maxloc ()** and **minloc ()** return locations of maximum and minimum value respectively
 - ▶ **cshift ()** performs a *circular* shift along an array dimension
 - ▶ **eoshift ()** perform a *end-off* shift along an array dimension
 - ▶ **spread ()** increases by one the rank of an array expression
 - ▶ **pack ()** selects elements from an array according to a mask and packs them in a rank-1 array
 - ▶ And **unpack ()** does the reverse
- ▶ But too much detail to cover in this introduction, look for them on your compiler documentation, and experiment

- ▶ Vector and matrix multiplication functions
 - ▶ `dot_product(vector_a, vector_b)`
 - ▶ `matmul(matrix_a, matrix_b)`
- ▶ But the BLAS libraries are around
 - ▶ Widely used
 - ▶ Highly optimized implementations available
- ▶ Outstanding compilers include special purpose, optimized BLAS version for those calls
- ▶ Good compilers do not include BLAS, but give option to link them for those calls
- ▶ Average compilers do not shine for those calls
- ▶ Our advice: install a reputedly good BLAS version and use it
- ▶ There is more to matrix algebra than matrix multiplies and vector products

- ▶ Re-write the Sieve of Eratosthenes algorithm using array syntax

Array Syntax

Input/Output

- File I/O

- Namelist

- Internal Files

- Unformatted I/O

- Robust I/O

Array Syntax

Input/Output

Formatted I/O

File I/O

Namelist

Internal Files

Unformatted I/O

Robust I/O

- ▶ Data are manipulated in internal (usually binary) format
- ▶ Fortran Standard leaves internal format details up to the implementation
- ▶ Formatted I/O translates internal representation of variables into human readable format
- ▶ Best practices:
 - ▶ Use formatted I/O just for small amount of data meant to be read by humans
 - ▶ Beware: human readable representation may cause problems because of rounding or not enough digits
 - ▶ Do not use I/O inside heavy computations: inhibits some code optimizations, and significantly affects performance

```

program golden_ratio

- ▶ The easiest way to do formatted I/O
- ▶ Specified using `*`
- ▶ Values are translated according to their types
- ▶ In the order they are listed on I/O statements
- ▶ No-nonsense, implementation dependent format
- ▶ Often outputs more digits than you actually care of
- ▶ Best practices:
 - ▶ Use it for terminal input
 - ▶ Use it for input of white-space separated values
 - ▶ Use it for quick output
 - ▶ Not suitable for rigid tabular formats

- ▶ Put you in total control of what is read/written

```

program golden_ratio
! experiments with the golden ratio iterative relation
  implicit none

 - ▶ string literals, usually in double quotes, emitted *as-is*
 - ▶ or proper *edit descriptors*, which dictate how a corresponding element on the I/O list should be converted
- ▶ *Repeat counts* can be used
 - ▶ Like in `5I3`, which will convert 5 **integer** values
 - ▶ Like in `2(I3,F7.4)`, which will convert 2 pairs, each made of an **integer** and a **real** value
- ▶ Formats must be specified on I/O statements
 - ▶ As a literal string, usually in single quotes
 - ▶ As a character expression
 - ▶ As a numeric label of a **format** statement in the same program unit (traditionally, before its end), reusable in many statements

- ▶ **A** is used to translate **character** values
 - ▶ **A** will emit the value as is
 - ▶ **A10** will emit 10 characters, truncating the value if longer, right justifying it if shorter
 - ▶ Beware: leading white-space skipped on input
 - ▶ Beware: **A10** and **10A** mean very different things!

- ▶ **A** is used to translate **character** values
 - ▶ **A** will emit the value as is
 - ▶ **A10** will emit 10 characters, truncating the value if longer, right justifying it if shorter
 - ▶ Beware: leading white-space skipped on input
 - ▶ Beware: **A10** and **10A** mean very different things!

- ▶ **I** is used to translate **integer** values
 - ▶ **I6** will emit up to 6 characters (sign included!), right justified with blanks
 - ▶ **I6.3** will emit 6 characters (sign included!), containing at least 3 (possibly zero) digits, right justified with blanks
 - ▶ Beware: again, **I10** and **10I** mean very different things!

- ▶ `F` can be used to translate `real` values
 - ▶ `F8.3` will emit up to 8 characters (sign and decimal point included!) in total, with 3 decimal digits (possibly zero), right justified with blanks
 - ▶ Beware: if `F6.2` is specified in input, and `-12345` is met, the value `-123.45` will be read in!
 - ▶ Beware: if `F6.2` is specified in input, and `-1.234` is met, the value `-1.234` will be read in anyhow!
- ▶ Beware of rounding: internal representation could have more precision than specified in edit descriptors

- ▶ **E** (or **D**) can also be used to translate `real` values
 - ▶ Exponential form is used (mantissa in the $[0,1)$ range)
 - ▶ Values $|x| < 10^{99}$, as -1.5372×10^{98} , will be converted like:
-.15372E+99
 - ▶ Values $|x| \geq 10^{99}$, as -1.5372×10^{99} , will be converted like:
-.15372+100
 - ▶ **E15.7** will emit up to 15 characters (sign, decimal point, and exponent field included!), with 7 decimal mantissa digits (possibly zero), right justified with blanks
 - ▶ Ditto for **E15.7E4**, except that 4 digits will be used for exponent
 - ▶ Again, input is more liberal

- ▶ **E** (or **D**) can also be used to translate `real` values
 - ▶ Exponential form is used (mantissa in the $[0,1)$ range)
 - ▶ Values $|x| < 10^{99}$, as -1.5372×10^{98} , will be converted like:
-.15372E+99
 - ▶ Values $|x| \geq 10^{99}$, as -1.5372×10^{99} , will be converted like:
-.15372+100
 - ▶ **E15.7** will emit up to 15 characters (sign, decimal point, and exponent field included!), with 7 decimal mantissa digits (possibly zero), right justified with blanks
 - ▶ Ditto for **E15.7E4**, except that 4 digits will be used for exponent
 - ▶ Again, input is more liberal
- ▶ And more can be used to the same purpose
 - ▶ Like **EN** (engineering notation), same as **E**, with exponent always multiple of 3
 - ▶ Like **G**, which uses the most suitable between **F** and **E**, depending on the value magnitude

- ▶ /
 - ▶ Forces a new line on output

- ▶ Items missing in the input will retain previous value

- ▶ **namelists** allow input/output of annotated lists of values
- ▶ Performed by **read** or **write** statements that do not have an I/O list and in which format is replaced by a namelist name
- ▶ File content is structured, self-describing, order independent, comments are allowed:

```
&golden_inputs  
tol=1.e-4      ! tolerance  
phi_start=5.0 ! 0th iteration  
max_iter=1000000 /
```

- ▶ Items missing in the input will retain previous value
- ▶ Items can be added to a namelist in different statements, but a code like this easily misleads readers (and you read your own codes, don't you?)

- ▶ **namelists** allow input/output of annotated lists of values
- ▶ Performed by **read** or **write** statements that do not have an I/O list and in which format is replaced by a namelist name
- ▶ File content is structured, self-describing, order independent, comments are allowed:

```
&golden_inputs  
tol=1.e-4      ! tolerance  
phi_start=5.0  ! 0th iteration  
max_iter=1000000 /
```

- ▶ Items missing in the input will retain previous value
- ▶ Items can be added to a namelist in different statements, but a code like this easily misleads readers (and you read your own codes, don't you?)
- ▶ Use them to make input robust, in output mostly good for debugging

- ▶ **character** variables of default kind can be specified in place of units in **read** and **write** statements

- ▶ **character** variables of default kind can be specified in place of units in **read** and **write** statements
- ▶ Writing to internal files is good to:
 - ▶ dynamically build file names according to a pattern (like number of iterations)
 - ▶ dynamically assemble complex I/O formats, depending on actual data
 - ▶ prepare complex labels for plot data formats
 - ▶ build commands to be sent to hardware devices
 - ▶ ...

- ▶ **character** variables of default kind can be specified in place of units in **read** and **write** statements
- ▶ Writing to internal files is good to:
 - ▶ dynamically build file names according to a pattern (like number of iterations)
 - ▶ dynamically assemble complex I/O formats, depending on actual data
 - ▶ prepare complex labels for plot data formats
 - ▶ build commands to be sent to hardware devices
 - ▶ ...
- ▶ Reading from internal files can be useful to read complex inputs
 - ▶ You have a textual input file sporting different formats
 - ▶ And the right format depends on actual data in the file
 - ▶ Just read each line in a **character** variable, suitably sized
 - ▶ Pick the suitable format
 - ▶ And use it to read from the variable itself

- ▶ Play with `goldenfile.f90`, `goldenfn1.f90`, and `goldenio.f90`:
 - ▶ writing input files
 - ▶ writing good and bad data in input files
 - ▶ giving input files wrong file names

- ▶ Formatted I/O is good, but:
 - ▶ internal data format is much more compact
 - ▶ and roundoff may happen, making recovery of original values impossible
 - ▶ and conversion takes time
- ▶ Unformatted I/O is used to store and recover data in internal representation
 - ▶ Just give **FORM='unformatted'** option when opening the file
 - ▶ And omit format in **read** and **write** statements

- ▶ Formatted I/O is good, but:
 - ▶ internal data format is much more compact
 - ▶ and roundoff may happen, making recovery of original values impossible
 - ▶ and conversion takes time
- ▶ Unformatted I/O is used to store and recover data in internal representation
 - ▶ Just give **FORM='unformatted'** option when opening the file
 - ▶ And omit format in **read** and **write** statements
- ▶ Unformatted I/O is performed on a *record* basis
 - ▶ In unformatted mode, each **write** writes a *record*
 - ▶ As we'll see, this allows walking your files backward and forward
 - ▶ But has interesting consequences, as more than your data is written to your file...

- ▶ Modify `itinv.f90` to perform unformatted I/O
- ▶ To test it, you'll need an additional program:
 - ▶ taking text input from keyboard or initializing all needed data
 - ▶ to write a good unformatted input file for the new version of `itinv.f90`

▶ Try different ways to output the results:

▶ element-wise

```
do j=1,n
  do i=1,n
    write(79) a(i,j)
  end do
end do
```

▶ column-wise, using an implied do-loop:

```
do j=1,n
  write(79) (a(i,j), i=1,n)    ! a(:,j) will also do
end do
```

▶ with two implied do-loops:

```
write(79) ((a(i,j), i=1,n), j=1,n)
```

▶ Can you spot the difference?

▶ Try different ways to output the results:

▶ element-wise

```
do j=1,n
  do i=1,n
    write(79) a(i,j)
  end do
end do
```

▶ column-wise, using an implied do-loop:

```
do j=1,n
  write(79) (a(i,j), i=1,n)    ! a(:,j) will also do
end do
```

▶ with two implied do-loops:

```
write(79) ((a(i,j), i=1,n), j=1,n)
```

▶ Can you spot the difference?

▶ Not a big issue for 4×4 matrices, but think of a $256 \times 256 \times 1024$ grid!

- ▶ **read** always advance to next record, even if you read only part of the record (or possibly nothing)
- ▶ **backspace (u)** moves position for subsequent I/Os to the record preceding the current one
- ▶ **rewind (u)** moves position for subsequent I/Os to file beginning
- ▶ To allow positioning back and forth, a four bytes record marker is added in 32 bit mode (eight bytes in 64 bit mode) before and after each record
- ▶ Best practice: write data in whole blocks

- ▶ Record markers added in unformatted I/O make exchanging data with other programs (notably C ones) troublesome
- ▶ `open (unit, ..., ACCESS='stream', ...)` is a new method to access external files
- ▶ No record markers are written before or after a `write`
 - ▶ Thus, advancing or backspacing over records is not possible
 - ▶ But required position may be specified by:

```
write(unit,POS=position) x  
read(unit,POS=position) y
```
- ▶ Best practice: if you are really serious about data exchanges, across different programs and systems, use libraries like HDF5, VTK, CGNS

Managing Memory

Conclusions

Extending the Language

Derived Types

Operators Overloading

Parameterized Types

Extending Types, and Objects

Managing Memory

Conclusions

- ▶ Fortran allows programmers to add new types, built as assemblies of existing ones

```
type position
  real :: x, y, z
end type position
```

```
type velocity
  real :: x, y, z
end type velocity
```

- ▶ Components in different derived types may have the same name (not a surprise!)
- ▶ **type(position) :: r** declares a variable of type **position**
- ▶ Components of a derived type can be accessed like this:
r%y = 0.0

- ▶ Derived types are not second class citizens
- ▶ Thus derived types (also termed *structures*) can be assembled from other derived types too

```

type particle
  type(position) :: r
  type(velocity) :: v
  real :: mass
end type particle
  
```

```

type atom
  type(position) :: r
  type(velocity) :: v
  real :: mass ! In atomic units
  integer :: an ! Atomic number
end type atom
  
```

- ▶ `type(particle) :: p` declares a variable of type `particle`
- ▶ Components of a component of a variable can be accessed like this: `p%v%z = 0.0`

```
type(atom) :: h1, h2, he

h1%r = position(0.0, 0.0, 0.0)
h1%v = velocity(1.0, -1.0, 0.0)
h1%mass = 1.00794
h1%an = 1 ! Assigns atomic number

h2 = h1 ! Intrinsic assignment

he = atom(position(1.0, 0.0, -1.0), h2%v, 4.002602, 2)
```

- ▶ Derived type name can be used to construct values of the type
- ▶ Unsurprisingly, `velocity()` is termed a *constructor*
- ▶ Values passed as argument to constructors must be ordered as in type definition
- ▶ Assignment is intrinsically available

- ▶ Derived types boil down (possibly recursively) to collections of intrinsic types
- ▶ And behavior is coherent with I/O of complex values and arrays
- ▶ All single intrinsic type (sub)components will be processed in sequence
- ▶ If you want control of the conversion:
 - ▶ a proper edit descriptor must be provided for each component
 - ▶ in same order as components are declared in type declaration
- ▶ Fortran 2003 introduces the **D_T** edit descriptor to give users total control

 - ▶ lowest for new binary operators
- ▶ Now velocities may be added as intrinsic arithmetic types
- ▶ And defining subtraction is an easy job
- ▶ Positions may be added as usual intrinsic variables and boundary conditions are automatically imposed
- ▶ Time for a module

A Module Centered on Derived Types

```

module periodic_box
  implicit none
  real, private, parameter :: boxwidth = 128.0
  private addpos, addvel, chsvel, subvel, subpos

  type position
    real :: x, y, z
  end type position

  type velocity
    real :: x, y, z
  end type velocity

  interface operator(+)
    module procedure addpos
    module procedure addvel
  end interface operator(+)
! ...
contains
  function addpos(p1, p2) ! Adds positions with periodic boundary conditions on x
    type(position), intent(in) :: p1, p2
    type(position) :: addpos
    addpos%x = modulo(p1%x+p2%x, boxwidth)
    addpos%y = modulo(p1%y+p2%y, boxwidth)
    addpos%z = modulo(p1%z+p2%z, boxwidth)
  end function addpos

  function addvel
    !...
  end function addvel
! ...
end module periodic_box

```

- ▶ Again, modules are the best way of grouping related stuff
- ▶ Again, with modules and module procedures we don't need to write interface blocks
- ▶ Modules let us hide implementation details
- ▶ Best practice: put structure definitions and related functions and operators in modules
 - ▶ Anyway, they will be used together
 - ▶ When dealing with nested types with many related functions, a hierarchy of modules would probably help
 - ▶ Because, of course, you can **use** modules in a module

- ▶ Write a module that defines:
 - ▶ A new type *vector* made up of three real components
 - ▶ Operator `.cross.` for cross product
 - ▶ Operator `+` to sum two *vectors*
- ▶ Write a program to test your module

```

program test_class_vector
  use class_vector

  implicit none

  type(vector) :: v, w, z

  v=vector(1.d0,0.d0,0.d0)
  w=vector(0.d0,1.d0,0.d0)
  z=vector(0.d0,0.d0,1.d0)

  write(*,*) v+w.cross.z

end program test_class_vector
  
```

- ▶ Definition of cross product:

$$a \times b = (a_2 b_3 - a_3 b_2) \hat{i} + (a_3 b_1 - a_1 b_3) \hat{j} + (a_1 b_2 - a_2 b_1) \hat{k}$$

- ▶ Then extend operators to have them work with array of vectors: it's elementary!

Extending the Language

Derived Types

Operators Overloading

Parameterized Types

Extending Types, and Objects

Managing Memory

Conclusions

- ▶ What if we wanted different **kinds of points**?

- ▶ This is a possibility:

```
type point
  real( selected_real_kind(5) ) :: x, y, z
end type point
```

```
type widepoint
  real( selected_real_kind(12) ) :: x, y, z
end type widepoint
```

- ▶ But not very elegant, nor easy to manage

- ▶ In Fortran 2003, types may have kind type parameters:

```
type point(point_kind)
  integer, kind :: point_kind = kind(0.0)
  real(point_kind) :: x, y, z
end type point
```

```
type(point(point_kind=kind(0.0))) :: apoint
type(point) :: anotherpoint
type(point(selected_real_kind(12))) :: awiderpoint
```

- ▶ **kind** states that this type parameter behaves as a kind
- ▶ And it works as **kind** does for intrinsic types

- ▶ Structures may have array components

```

type segments(point_kind)
  integer, kind :: point_kind = kind(0.0)
  type(point(point_kind)), dimension(100) :: start_point
  type(point(point_kind)), dimension(100) :: end_point
end type segments
  
```

- ▶ Our `segments` type looks a bit rigid, doesn't it?

- ▶ Derived type parameters come to rescue:

```

type segments(point_kind, n)
  integer, kind :: point_kind = kind(0.0)
  integer, len :: n
  type(point(point_kind)), dimension(n) :: start_point
  type(point(point_kind)), dimension(n) :: end_point
end type segments
  
```

```

type(segments(n=100)) :: ahundredsegments
type(segments(n=1000)) :: athousandsegments
  
```

Extending Types, and Objects

Managing Memory

Conclusions

- ▶ So, we are able to define new types, and specialized procedures and operators to use them

- ▶ So, we are able to define new types, and specialized procedures and operators to use them
- ▶ This is what Computer Science priests term *Object-Based* programming

- ▶ So, we are able to define new types, and specialized procedures and operators to use them
- ▶ This is what Computer Science priests term *Object-Based* programming
- ▶ But **point**, **position**, and **velocity** have the same components
 - ▶ And that's always true, whatever the space dimensions
 - ▶ But they are conceptually (and dimensionally!) different things

- ▶ So, we are able to define new types, and specialized procedures and operators to use them
- ▶ This is what Computer Science priests term *Object-Based* programming
- ▶ But **point**, **position**, and **velocity** have the same components
 - ▶ And that's always true, whatever the space dimensions
 - ▶ But they are conceptually (and dimensionally!) different things
- ▶ And **particle**, and **atom** share identical components
 - ▶ And a **ion** would simply add a **charge** component

- ▶ So, we are able to define new types, and specialized procedures and operators to use them
- ▶ This is what Computer Science priests term *Object-Based* programming
- ▶ But **point**, **position**, and **velocity** have the same components
 - ▶ And that's always true, whatever the space dimensions
 - ▶ But they are conceptually (and dimensionally!) different things
- ▶ And **particle**, and **atom** share identical components
 - ▶ And a **ion** would simply add a **charge** component
- ▶ Wouldn't it be nice to 'inherit' from one type to another?
 - ▶ Yeah, and easier to manage, too!
 - ▶ And this is what CS priests call *Object-Oriented* programming, and is so trendy!

```
type point
  real :: x, y, z
end type point

type, extends(point) :: position
end type position

type, extends(point) :: velocity
end type velocity

type particle
  type(position) :: r
  type(velocity) :: v
  real :: mass
end type particle

type, extends(particle) :: atom
  integer :: an ! atomic number
end type atom

type, extends(atom) :: ion
  integer :: charge ! in units of elementary charge
end type ion
```

- ▶ **extends** means that the new type has the same components, and possibly more
- ▶ Now we still have to write procedures and operators, don't we?

- ▶ A type extension includes an implicit component with the same name and type as its parent type
 - ▶ this can come in handy when the programmer wants to operate on components specific to a parent type

```
type(ion) :: p                ! declare p as a ion object

p%mass                       ! access mass component for p
p%atom%mass                  ! another way
p%atom%particle%mass        ! ...
```

- ▶ We often say the child and parent types have a “is a” relationship
 - ▶ an atom “is” a particle
 - ▶ but a particle is not an atom because the atomic component may be found in atom but not in particle

- ▶ Consider the case you have to evolve the position of a particle according to a given velocity field
 - ▶ atoms or ions may behave in the (nearly) same way wrt this evolution
 - ▶ and you do not want to write two (nearly) identical procedures for the two types

- ▶ Polymorphic procedures are the right way
 - ▶ i.e., procedures which can take one or more polymorphic variables as arguments
 - ▶ “polymorphic variable” = variable whose data type is dynamic at runtime
 - ▶ the **class** keyword allows F2003 programmers to create polymorphic variables
 - ▶ use it for dummy arguments (the simplest usage, not the only one)

```

subroutine setMass(p, m)
class(particle) :: p
real, intent(in) :: m
p%mass = m
end subroutine setMass
  
```

- ▶ The **p** dummy argument is polymorphic, based on the usage of **class(particle)**
- ▶ The subroutine can operate on objects that satisfy the "is a" particle relationship
 - ▶ **setMass** can be called passing a particle, atom, ion, or any future type extension of particle

```

type(particle) :: pa      ! declare an instance of particle
type(atom)     :: at     ! declare an instance of atom
type(ion)      :: io     ! declare an instance of ion
  
```

```

call setMass(pa, mm)     ! set the mass for a particle
call setMass(at, mm)    ! set the mass for an atom
call setMass(io, mm)    ! set the mass for a ion
  
```

- ▶ By default, only those components found in the declared type of an object are accessible

- ▶ By default, only those components found in the declared type of an object are accessible
 - ▶ e.g., only mass, r, v are accessible for p declared as **class (particle)**

- ▶ By default, only those components found in the declared type of an object are accessible
 - ▶ e.g., only mass, r, v are accessible for p declared as `class (particle)`
- ▶ To access the components of the dynamic type, the `select type` construct is required

- ▶ By default, only those components found in the declared type of an object are accessible
 - ▶ e.g., only mass, r, v are accessible for p declared as **class (particle)**
- ▶ To access the components of the dynamic type, the **select type** construct is required
 - ▶ and optional arguments come in handy

Selecting type

```
subroutine initialize(p, mm, rr, vv, aan, ccharge)
class(particle) :: p
real :: mm
type(position) :: rr
type(velocity) :: vv
integer, optional :: aan, ccharge
p%mass = mm
p%r = rr
p%v = vv
select type (p)
type is (particle)
    ! no further initialization required
class is (atom)
    ! atom or ion specific initializations
    if (present(aan)) then
        p%an = aan
    else
        p%an = 1
    endif
class is (ion)
    if (present(ccharge)) then
        p%charge = ccharge
    else
        p%charge = 0
    endif
class default
    ! give error for unexpected/unsupported type
    stop 'initialize: unexpected type for p object!'
end select
end subroutine initialize
```

- ▶ By default, only those components found in the declared type of an object are accessible
 - ▶ e.g., only mass, r, v are accessible for p declared as **class (particle)**
- ▶ To access the components of the dynamic type, the **select type** construct is required
 - ▶ and optional arguments come in handy
- ▶ There are two styles of type checks that we can perform

- ▶ By default, only those components found in the declared type of an object are accessible
 - ▶ e.g., only mass, r, v are accessible for p declared as **class (particle)**
- ▶ To access the components of the dynamic type, the **select type** construct is required
 - ▶ and optional arguments come in handy
- ▶ There are two styles of type checks that we can perform
 - ▶ **type is**: satisfied if the dynamic type of the object is the same as the type specified in parentheses

- ▶ By default, only those components found in the declared type of an object are accessible
 - ▶ e.g., only mass, r, v are accessible for p declared as **class (particle)**
- ▶ To access the components of the dynamic type, the **select type** construct is required
 - ▶ and optional arguments come in handy
- ▶ There are two styles of type checks that we can perform
 - ▶ **type is**: satisfied if the dynamic type of the object is the same as the type specified in parentheses
 - ▶ **class is**: satisfied if the dynamic type of the object is the same or an extension of the specified type in parentheses

Selecting type

```
subroutine initialize(p, mm, rr, vv, aan, ccharge)
class(particle) :: p
real :: mm
type(position) :: rr
type(velocity) :: vv
integer, optional :: aan, ccharge
p%mass = mm
p%r = rr
p%v = vv
select type (p)
type is (particle)
    ! no further initialization required
class is (atom)
    ! atom or ion specific initializations
    if (present(aan)) then
        p%an = aan
    else
        p%an = 1
    endif
class is (ion)
    if (present(ccharge)) then
        p%charge = ccharge
    else
        p%charge = 0
    endif
class default
    ! give error for unexpected/unsupported type
    stop 'initialize: unexpected type for p object!'
end select
end subroutine initialize
```

- ▶ By default, only those components found in the declared type of an object are accessible

 - ▶ **type is**: satisfied if the dynamic type of the object is the same as the type specified in parentheses
 - ▶ **class is**: satisfied if the dynamic type of the object is the same or an extension of the specified type in parentheses
- ▶ Best practice: add a **class default** branch and print error when p is not an extension of **particle** type

- ▶ By default, only those components found in the declared type of an object are accessible
 - ▶ e.g., only mass, r, v are accessible for p declared as **class (particle)**
- ▶ To access the components of the dynamic type, the **select type** construct is required
 - ▶ and optional arguments come in handy
- ▶ There are two styles of type checks that we can perform
 - ▶ **type is**: satisfied if the dynamic type of the object is the same as the type specified in parentheses
 - ▶ **class is**: satisfied if the dynamic type of the object is the same or an extension of the specified type in parentheses
- ▶ Best practice: add a **class default** branch and print error when p is not an extension of **particle** type
 - ▶ an empty **type is (particle)** branch may be required to avoid getting error when p is only a particle

Selecting type

```
subroutine initialize(p, mm, rr, vv, aan, ccharge)
class(particle) :: p
real :: mm
type(position) :: rr
type(velocity) :: vv
integer, optional :: aan, ccharge
p%mass = mm
p%r = rr
p%v = vv
select type (p)
type is (particle)
    ! no further initialization required
class is (atom)
    ! atom or ion specific initializations
    if (present(aan)) then
        p%an = aan
    else
        p%an = 1
    endif
class is (ion)
    if (present(ccharge)) then
        p%charge = ccharge
    else
        p%charge = 0
    endif
class default
    ! give error for unexpected/unsupported type
    stop 'initialize: unexpected type for p object!'
end select
end subroutine initialize
```

- ▶ Objects in Fortran 2003
 - ▶ A Fortran 90/95 module can be viewed as an object because it can encapsulate both data and procedures
 - ▶ But, derived types in F2003 are considered objects because they now can encapsulate data as well as procedures
 - ▶ Modules and types work together...
- ▶ Procedures encapsulated in a derived type are called type-bound procedures (“methods” in OO jargon)

```
type particle
  type(position) :: r
  type(velocity) :: v
  real :: mass
  contains
    procedure :: initialize => initialize_particle
end type particle
```

- ▶ **initialize_particle** is the name of the underlying procedure to be implemented
- ▶ Explicit interface is required: wrap in a module!

► Employing modules and types to design objects

```

module particle_mod
  type particle
    type(position) :: r
    type(velocity) :: v
    real :: mass
  contains
    procedure :: initialize => initialize_particle
  end type particle
  type, extends(particle) :: atom
  ...
end type atom
  type, extends(atom) :: ion
  ...
end type ion
  contains
  ! insert the implementation or at least the interface of initialize_particle
  subroutine initialize_particle(p, mm, rr, vv, aan, ccharge)
  class(particle) :: p
  ...
  end subroutine initialize_particle
end module particle_mod
  
```

- ▶ `initialize` is the name to be used to invoke the type bound procedure

```

use particle_mod
type(particle) :: p           ! declare an instance of particle
call p%initialize(mas, pos, vel) ! initialize particle
  
```

- ▶ What about the first dummy argument of `initialize`?

- ▶ it is known as the *passed-object* dummy argument
- ▶ must be declared `class` and of the same type as the derived type that defined the type-bound procedure
- ▶ by default, it is the first dummy argument in the type-bound procedure: it receives the object that invoked the type-bound procedure

- ▶ It is possible to pass another argument in place of the first one

```
procedure, pass(p) :: initialize
```

- ▶ ...or to avoid passing it at all

```
procedure, nopass :: initialize
```

- ▶ A child type inherits or reuses components from their parent or ancestor types: this applies to both data and procedures

```

type(particle) :: pa           ! declare an instance of particle
type(atom)     :: at           ! declare an instance of atom
type(ion)      :: io           ! declare an instance of ion
call pa%initialize(mas, pos, vel) ! initialize a particle
call at%initialize(mas, pos, vel, anu) ! initialize an atom
call io%initialize(mas, pos, vel, anu, cha) ! initialize a ion
  
```

- ▶ **initialize** behaves accordingly to the passed arguments, i.e. using **optional** and **select type** features
- ▶ Sometimes, another approach may be more appropriate: overriding!

```
module particle_mod
  type particle
    type(position) :: r
    type(velocity) :: v
    real :: mass
    contains
      procedure :: initialize => initialize_particle
  end type particle
  type, extends(particle) :: atom
  ...
  contains
    procedure :: initialize => initialize_atom
  end type atom
  type, extends(atom) :: ion
  ...
end type ion
contains
! insert the implementation or at least the interface of initialize
subroutine initialize_particle(p, mm, rr, vv, aan, cch)
class(particle) :: p
...
end subroutine initialize_particle
subroutine initialize_atom(p, mm, rr, vv, aan, cch)
class(atom) :: p
...
end subroutine initialize_atom
end module particle_mod
```

```
type(particle) :: pa           ! declare an instance of particle
type(atom)      :: at         ! declare an instance of atom
type(ion)       :: io         ! declare an instance of ion
call pa%initialize(mas, pos, vel) ! calls initialize_particle
call at%initialize(mas, pos, vel, anu) ! calls initialize_atom
call io%initialize(mas, pos, vel, anu, cha) ! calls initialize_atom
```

- ▶ Beware: an overriding type-bound procedure must have exactly the same interface as the overridden procedure except for the passed-object dummy argument which must be **class(new-type)**
 - ▶ optional arguments may hide useless arguments

```

module particle_mod
type particle
  type(position) :: r
  type(velocity) :: v
  real :: mass
  contains
    procedure :: initialize => initialize_particle
end type particle
type, extends(particle) :: atom
  ...
  contains
    procedure :: initialize => initialize_atom
end type atom
type, extends(atom) :: ion
  ...
end type ion
contains
! insert the implementation or at least the interface of initialize
subroutine initialize_particle(p, mm, rr, vv, aan, cch)
class(particle) :: p
  ...
end subroutine initialize_particle
subroutine initialize_atom(p, mm, rr, vv, aan, cch)
class(atom) :: p
  ...
end subroutine initialize_atom
end module particle_mod
  
```

```
type(particle) :: pa           ! declare an instance of particle
type(atom)      :: at         ! declare an instance of atom
type(ion)       :: io         ! declare an instance of ion
call pa%initialize(mas, pos, vel) ! calls initialize_particle
call at%initialize(mas, pos, vel, anu) ! calls initialize_atom
call io%initialize(mas, pos, vel, anu, cha) ! calls initialize_atom
```

- ▶ Beware: an overriding type-bound procedure must have exactly the same interface as the overridden procedure except for the passed-object dummy argument which must be **class (new-type)**
 - ▶ optional arguments may hide useless arguments
- ▶ Of course, it is still possible to explicitly invoke the version defined by a parent type instead of the overridden one

```

type(particle) :: pa           ! declare an instance of particle
type(atom)      :: at         ! declare an instance of atom
type(ion)       :: io         ! declare an instance of ion
call pa%initialize(mas, pos, vel) ! calls initialize_particle
call at%initialize(mas, pos, vel, anu) ! calls initialize_atom
call io%initialize(mas, pos, vel, anu, cha) ! calls initialize_atom
  
```

- ▶ Beware: an overriding type-bound procedure must have exactly the same interface as the overridden procedure except for the passed-object dummy argument which must be **class (new-type)**
 - ▶ optional arguments may hide useless arguments
- ▶ Of course, it is still possible to explicitly invoke the version defined by a parent type instead of the overridden one
- ▶ And it is possible to prevent any type extensions from overriding a particular type-bound procedure

```
procedure, non_overridable :: initialize
```

- ▶ Information hiding allows the programmer to view an object and its procedures as a “black box”
 - ▶ procedure overriding is a first example of information hiding, **initialize** has different “hidden” implementations depending on the calling object

- ▶ Information hiding allows the programmer to view an object and its procedures as a “black box”
 - ▶ procedure overriding is a first example of information hiding, **initialize** has different “hidden” implementations depending on the calling object
- ▶ Hiding data:
 - ▶ safer against data corruption: the user may modify data only through adequate procedures
 - ▶ changes to the data structure will not affect codes using our class provided that we don't change interfaces

- ▶ Information hiding allows the programmer to view an object and its procedures as a “black box”

```

Or

```
type flow
   real(rk) :: u,v,w,p
end type
```

```
type(flow) :: f(NX,NY,NZ)
```

Which one is best?

A Recurrent Issue: SoA or AoS

```
► type flow
  real(rk) :: u(NX,NY,NZ)
  real(rk) :: v(NX,NY,NZ)
  real(rk) :: w(NX,NY,NZ)
  real(rk) :: p(NX,NY,NZ)
end type
```

```
type(flow) :: f
```

Or

```
type flow
  real(rk) :: u,v,w,p
end type
```

```
type(flow) :: f(NX,NY,NZ)
```

Which one is best?

► Both have merits

A Recurrent Issue: SoA or AoS

```
► type flow
  real(rk) :: u(NX,NY,NZ)
  real(rk) :: v(NX,NY,NZ)
  real(rk) :: w(NX,NY,NZ)
  real(rk) :: p(NX,NY,NZ)
end type
```

```
type(flow) :: f
```

Or

```
type flow
  real(rk) :: u,v,w,p
end type
```

```
type(flow) :: f(NX,NY,NZ)
```

Which one is best?

- Both have merits
- The choice strongly depends on the computer architecture

A Recurrent Issue: SoA or AoS

```
► type flow
  real(rk) :: u(NX,NY,NZ)
  real(rk) :: v(NX,NY,NZ)
  real(rk) :: w(NX,NY,NZ)
  real(rk) :: p(NX,NY,NZ)
end type
```

```
type(flow) :: f
```

Or

```
type flow
  real(rk) :: u,v,w,p
end type
```

```
type(flow) :: f(NX,NY,NZ)
```

Which one is best?

- Both have merits
- The choice strongly depends on the computer architecture
 - for cache-based CPUs the choice is difficult (it depends on the order of the accesses of your numerical scheme)

A Recurrent Issue: SoA or AoS

```
▶ type flow
  real(rk) :: u(NX,NY,NZ)
  real(rk) :: v(NX,NY,NZ)
  real(rk) :: w(NX,NY,NZ)
  real(rk) :: p(NX,NY,NZ)
end type
```

```
type(flow) :: f
```

Or

```
type flow
  real(rk) :: u,v,w,p
end type
```

```
type(flow) :: f(NX,NY,NZ)
```

Which one is best?

- ▶ Both have merits
- ▶ The choice strongly depends on the computer architecture
 - ▶ for cache-based CPUs the choice is difficult (it depends on the order of the accesses of your numerical scheme)
 - ▶ but using GPUs or MICs the first one is usually better!

```
subroutine my_pde_solver(nx, ny, nz)
  integer, intent(in) :: nx, ny, nz

  integer, parameter :: rk = selected_real_kind(12)
  real(rk) :: deltax, deltay, deltaz ! Grid steps

  real(rk) :: u(nx,ny,nz)
  real(rk) :: v(nx,ny,nz)
  real(rk) :: w(nx,ny,nz)
  real(rk) :: p(nx,ny,nz)
```

- We could think of declaring automatic arrays inside a subroutine

```
subroutine my_pde_solver(nx, ny, nz)
  integer, intent(in) :: nx, ny, nz

  integer, parameter :: rk = selected_real_kind(12)
  real(rk) :: deltax, deltay, deltaz ! Grid steps

  real(rk) :: u(nx,ny,nz)
  real(rk) :: v(nx,ny,nz)
  real(rk) :: w(nx,ny,nz)
  real(rk) :: p(nx,ny,nz)
```

- ▶ We could think of declaring automatic arrays inside a subroutine
- ▶ This is unwise
 - ▶ Automatic arrays are usually allocated on the process stack
 - ▶ Which is a precious resource
 - ▶ And limited in most system configurations

A Bad, Old, Common approach

```
program pde_solve
  parameter (MAXNX=400, MAXNY=400, MAXNZ=400)
  parameter (MAXSIZE=MAXNX*MAXNX*MAXNZ)

  real*8 u(MAXSIZE), v(MAXSIZE), w(MAXSIZE), p(MAXSIZE)

  common u, v, w, p
! ...
  call my_pde_solver(nx, ny, nz, u, v, w, p)
! ...
end

subroutine my_pde_solver(nx, ny, nz, u, v, w, p)
  real*8 u(nx, ny, nz), v(nx, ny, nz), w(nx, ny, nz), p(nx, ny, nz)
!...
```

- ▶ We could give a different shape to dummy arguments

A Bad, Old, Common approach

```

program pde_solve
  parameter (MAXNX=400, MAXNY=400, MAXNZ=400)
  parameter (MAXSIZE=MAXNX*MAXNX*MAXNZ)

  real*8 u (MAXSIZE) , v (MAXSIZE) , w (MAXSIZE) , p (MAXSIZE)

  common u, v, w, p
! ...
  call my_pde_solver (nx, ny, nz, u, v, w, p)
! ...
end

subroutine my_pde_solver (nx, ny, nz, u, v, w, p)
  real*8 u (nx, ny, nz) , v (nx, ny, nz) , w (nx, ny, nz) , p (nx, ny, nz)
!...

```

- ▶ We could give a different shape to dummy arguments
- ▶ But this only works if interface is implicit
 - ▶ Which is dangerous

A Bad, Old, Common approach

```

program pde_solve
  parameter (MAXNX=400, MAXNY=400, MAXNZ=400)
  parameter (MAXSIZE=MAXNX*MAXNX*MAXNZ)

  real*8 u (MAXSIZE) , v (MAXSIZE) , w (MAXSIZE) , p (MAXSIZE)

  common u, v, w, p
! ...
  call my_pde_solver (nx, ny, nz, u, v, w, p)
! ...
end

subroutine my_pde_solver (nx, ny, nz, u, v, w, p)
  real*8 u (nx, ny, nz) , v (nx, ny, nz) , w (nx, ny, nz) , p (nx, ny, nz)
!...

```

- ▶ We could give a different shape to dummy arguments
- ▶ But this only works if interface is implicit
 - ▶ Which is dangerous
- ▶ Maximum problem size still program limited: $nx*ny*nz$ must be less than **MAXSIZE**

- ▶ Being program limited is annoying
- ▶ It's much better to accommodate to any user specified problem size
 - ▶ Right, as long as there is enough memory
 - ▶ But if memory is not enough, not our fault
 - ▶ It's computer or user's fault
- ▶ And there are many complex kinds of computations
 - ▶ Those in which memory need cannot be foreseen in advance
 - ▶ Those in which arrays do not fit
 - ▶ Those in which very complex data structures are needed

Extending the Language

Managing Memory

Dynamic Memory Allocation

Fortran Pointers

Sketchy Ideas on Data Structures

Bridging the Gap with C

Conclusions

Enter Allocatable Arrays

```
integer, parameter :: rk = selected_real_kind(12)

real(rk), dimension(:, :, :), allocatable :: u, v, w, p

allocate (u (nx, ny, nz), v (nx, ny, nz), w (nx, ny, nz), p (nx, ny, nz))
```

- ▶ When allocatable arrays are declared, only their rank is specified (`dimension (:, :, :)`)

Enter Allocatable Arrays

```
integer, parameter :: rk = selected_real_kind(12)

real(rk), dimension(:, :, :), allocatable :: u, v, w, p

allocate (u (nx, ny, nz), v (nx, ny, nz), w (nx, ny, nz), p (nx, ny, nz))
```

- ▶ When allocatable arrays are declared, only their rank is specified (**dimension** (:, :, :))
- ▶ **allocate** statement performs actual memory allocation and defines extents

Enter Allocatable Arrays

```
integer, parameter :: rk = selected_real_kind(12)

real(rk), dimension(:, :, :), allocatable :: u, v, w, p

allocate (u (nx, ny, nz), v (nx, ny, nz), w (nx, ny, nz), p (nx, ny, nz))
```

- ▶ When allocatable arrays are declared, only their rank is specified (**dimension** (:, :, :))
- ▶ **allocate** statement performs actual memory allocation and defines extents
 - ▶ On failure, program **stops**

Enter Allocatable Arrays

```
integer, parameter :: rk = selected_real_kind(12)

real(rk), dimension(:, :, :), allocatable :: u, v, w, p

allocate (u (nx, ny, nz), v (nx, ny, nz), w (nx, ny, nz), p (nx, ny, nz))
```

- ▶ When allocatable arrays are declared, only their rank is specified (`dimension(:, :, :)`)
- ▶ `allocate` statement performs actual memory allocation and defines extents
 - ▶ On failure, program `stops`
 - ▶ But if `STAT=integer_var` is specified, `integer_var` is set to zero on success and to a positive value on failure, and execution doesn't stop

```
integer, parameter :: rk = selected_real_kind(12)

real(rk), dimension(:, :, :), allocatable :: u, v, w, p

allocate (u (nx, ny, nz) , v (nx, ny, nz) , w (nx, ny, nz) , p (nx, ny, nz) )
```

- ▶ When allocatable arrays are declared, only their rank is specified (`dimension (:, :, :)`)
- ▶ `allocate` statement performs actual memory allocation and defines extents
 - ▶ On failure, program `stops`
 - ▶ But if `STAT=integer_var` is specified, `integer_var` is set to zero on success and to a positive value on failure, and execution doesn't stop
- ▶ Best practice: use `STAT=` and, on failure, provide information to users before terminating execution

- ▶ Where all these 'dynamic allocated memory' comes from?
 - ▶ From an internal area, often termed "*memory heap*"
 - ▶ When that is exhausted, OS is asked to give the process more memory
 - ▶ And if OS is short of memory, or some configuration limit is exhausted...

- ▶ Where all these 'dynamic allocated memory' comes from?
 - ▶ From an internal area, often termed "*memory heap*"
 - ▶ When that is exhausted, OS is asked to give the process more memory
 - ▶ And if OS is short of memory, or some configuration limit is exhausted...
- ▶ When you are done with an allocatable, use **deallocate** to claim memory back
 - ▶ Allocatable which are local to a procedure are automatically deallocated on return
 - ▶ But it's implementation defined what happens to allocatable private to a module

- ▶ Where all these 'dynamic allocated memory' comes from?
 - ▶ From an internal area, often termed "*memory heap*"
 - ▶ When that is exhausted, OS is asked to give the process more memory
 - ▶ And if OS is short of memory, or some configuration limit is exhausted...
- ▶ When you are done with an allocatable, use **deallocate** to claim memory back
 - ▶ Allocatable which are local to a procedure are automatically deallocated on return
 - ▶ But it's implementation defined what happens to allocatable private to a module
- ▶ Best practice: always deallocate when you are done with an allocatable array

Three Common Mistakes

- ▶ Trying to allocate or deallocate an array that was not allocatable

Three Common Mistakes

- ▶ Trying to allocate or deallocate an array that was not allocatable
 - ▶ Compiler will catch it

Three Common Mistakes

- ▶ Trying to allocate or deallocate an array that was not allocatable
 - ▶ Compiler will catch it

- ▶ Trying to allocate or deallocate an array that was not deallocated or allocated respectively

Three Common Mistakes

- ▶ Trying to allocate or deallocate an array that was not allocatable
 - ▶ Compiler will catch it
- ▶ Trying to allocate or deallocate an array that was not deallocated or allocated respectively
 - ▶ Compiler can't catch it, runtime error

Three Common Mistakes

- ▶ Trying to allocate or deallocate an array that was not allocatable
 - ▶ Compiler will catch it
- ▶ Trying to allocate or deallocate an array that was not deallocated or allocated respectively
 - ▶ Compiler can't catch it, runtime error
 - ▶ In some cases (error recovery) use logical `allocated()` function to check

Three Common Mistakes

- ▶ Trying to allocate or deallocate an array that was not allocatable
 - ▶ Compiler will catch it
- ▶ Trying to allocate or deallocate an array that was not deallocated or allocated respectively
 - ▶ Compiler can't catch it, runtime error
 - ▶ In some cases (error recovery) use logical `allocated()` function to check
- ▶ Mistaking allocatables for a substitute to procedure automatic arrays

- ▶ Trying to allocate or deallocate an array that was not allocatable
 - ▶ Compiler will catch it
- ▶ Trying to allocate or deallocate an array that was not deallocated or allocated respectively
 - ▶ Compiler can't catch it, runtime error
 - ▶ In some cases (error recovery) use logical `allocated()` function to check
- ▶ Mistaking allocatables for a substitute to procedure automatic arrays
 - ▶ Dynamic allocation incurs costs

- ▶ Trying to allocate or deallocate an array that was not allocatable
 - ▶ Compiler will catch it
- ▶ Trying to allocate or deallocate an array that was not deallocated or allocated respectively
 - ▶ Compiler can't catch it, runtime error
 - ▶ In some cases (error recovery) use logical `allocated()` function to check
- ▶ Mistaking allocatables for a substitute to procedure automatic arrays
 - ▶ Dynamic allocation incurs costs
 - ▶ Only worth for big arrays that would not fit program stack

- ▶ When assigning an array value to a not allocated allocatable array, the allocatable array gets automatically allocated
- ▶ This simplifies the use of array functions which return a variable-sized result

```
real, dimension(100) :: x
real, allocatable, dimension(:) :: all_values, nonzero_values

! size is 100, small benefit wrt explicit allocation
all_values      = x

! size depends on x values, AA is a great benefit now
nonzero_values = pack(x,x/=0)
```

- ▶ Also useful when dealing with allocatable components in a derived type

- ▶ When assigning an array value to a not allocated allocatable array, the allocatable array gets automatically allocated
- ▶ This simplifies the use of array functions which return a variable-sized result

```
real, dimension(100) :: x
real, allocatable, dimension(:) :: all_values, nonzero_values

! size is 100, small benefit wrt explicit allocation
all_values      = x

! size depends on x values, AA is a great benefit now
nonzero_values = pack(x,x/=0)
```

- ▶ Also useful when dealing with allocatable components in a derived type
 - ▶ avoids separate coding for each allocatable component

- ▶ Automatic re-allocation is performed when the shape of the assignment does not fit, e.g.
 - `a = (/ a , 5 , 6 /)`
- ▶ Beware: it may dramatically affect performances!
 - ▶ if you don't need it, disable it using compiler options
- ▶ AA naturally extends to **characters** strongly increasing their adaptability
 - ▶ when declaring **characters**, the **len** value declaration may be postponed (**deferred type parameter**)
 - ▶ during assignment the Right Hand Side passes its **len** on the deferred-length string (under the hood, automatic re-allocation may occur)
 - ▶ explicit allocation is possible but often worthless, required when reading from input, though

```

character(len=:), allocatable :: str
character(len=50) :: fixed_str
allocate(character(80) :: str) ! allocates str using len=80
str = fixed_str ! re-allocates str using len=50
  
```

Extending the Language

Managing Memory

Dynamic Memory Allocation

Fortran Pointers

Sketchy Ideas on Data Structures

Bridging the Gap with C

Conclusions

- ▶ Fortran pointers are aliases to other objects
- ▶ Declared like regular variables, with attribute **pointer**
- ▶ Associated to actual objects with pointer assignment =>
- ▶ To be associated with a pointer, variables must have the **target** attribute
 - ▶ But compilers are often liberal (sloppy?) on this
- ▶ Disassociated by actual objects with **nullify** statement or by pointer assignment of **null()**

```
real, dimension(:, :, :), pointer :: r
```

```
real, target :: a(5,15,6), b(3,22,7)
```

```

r => a           ! pointer assignment
                ! now r is an alias of a
r(1,1,1) = 2.   ! usual assignment
                ! now both r(1,1,1) and a(1,1,1) values are 2.
nullify(r)      ! a is still alive

```

```

r => b           ! now r is an alias of b
r => null()

```

► Let us clarify

```
real, dimension(:), pointer :: p
```

does not declare an array of pointers, but a pointer capable of aliasing an array

- ▶ Let us clarify

```
real, dimension(:), pointer :: p
```

does not declare an array of pointers, but a pointer capable of aliasing an array

- ▶ What about array of pointers?

- ▶ Let us clarify

```
real, dimension(:), pointer :: p
```

does not declare an array of pointers, but a pointer capable of aliasing an array

- ▶ What about array of pointers?

- ▶ as such are not allowed in Fortran, but the equivalent effect can be achieved by creating a type containing a pointer component and building an array of this type

- ▶ Let us clarify

```
real, dimension(:), pointer :: p
```

does not declare an array of pointers, but a pointer capable of aliasing an array

- ▶ What about array of pointers?

- ▶ as such are not allowed in Fortran, but the equivalent effect can be achieved by creating a type containing a pointer component and building an array of this type

- ▶ For example, a lower-triangular matrix may be held using a pointer for each row

```
type row
  real, dimension(:), pointer :: r
end type row
type(row), dimension(n) :: t
do i=1,n
  allocate(t(i)%r(1:i)) ! Allocate row i of length i
enddo
```

► Pointers may also alias subobjects

```
real, dimension(:, :, :), pointer :: r
type(velocity), pointer :: v
real, target :: a(5, 15, 6)
type(atom), target :: oneatom

r => a(2:4, 1:10, 3:6) ! r(1, 1, 1) aliases a(2, 1, 3)
                        ! r(3, 10, 4) aliases a(4, 10, 6)
v => oneatom%velocity
```

- ▶ Pointers may also alias subobjects

```
real, dimension(:, :, :), pointer :: r
type(velocity), pointer :: v
real, target :: a(5,15,6)
type(atom), target :: oneatom

r => a(2:4,1:10,3:6) ! r(1,1,1) aliases a(2,1,3)
                    ! r(3,10,4) aliases a(4,10,6)
v => oneatom%velocity
```

- ▶ The reverse is not true: it is not possible to explicitly associate sections of pointers

- ▶ Pointers may also alias subobjects

```

real, dimension(:, :, :), pointer :: r
type(velocity), pointer :: v
real, target :: a(5,15,6)
type(atom), target :: oneatom

r => a(2:4,1:10,3:6) ! r(1,1,1) aliases a(2,1,3)
                    ! r(3,10,4) aliases a(4,10,6)
v => oneatom%velocity
  
```

- ▶ The reverse is not true: it is not possible to explicitly associate sections of pointers
- ▶ But lower bounds may be specified (from F2003)

```

s(2:, :, :) => a(2:4,1:10,3:6) ! s(2,1,1) aliases a(2,1,3)
  
```

- ▶ Pointers may also alias subobjects

```

real, dimension(:, :, :), pointer :: r
type(velocity), pointer :: v
real, target :: a(5,15,6)
type(atom), target :: oneatom

r => a(2:4,1:10,3:6) ! r(1,1,1) aliases a(2,1,3)
                    ! r(3,10,4) aliases a(4,10,6)
v => oneatom%velocity
  
```

- ▶ The reverse is not true: it is not possible to explicitly associate sections of pointers
- ▶ But lower bounds may be specified (from F2003)
- ▶ A target of a multidimensional array pointer may be one-dimensional

```

a(1:n,1:n) => a_linear(1:n*n)
  
```

- If you allocate a pointer, an unnamed object of the pointee type is created, and associated with the pointer itself

```
real, dimension(:,:,:), pointer :: r  
type(atom_list), pointer :: first
```

```
allocate(r(5,15,6))
```

```
! now r refers an unnamed array allocated on the heap
```

```
allocate(first)
```

```
! now first refers to an unnamed type(atom_list) variable,  
! allocated on the heap
```

- ▶ If you allocate a pointer, an unnamed object of the pointee type is created, and associated with the pointer itself

```
real, dimension(:, :, :), pointer :: r  
type(atom_list), pointer :: first
```

```
allocate(r(5, 15, 6))
```

```
! now r refers an unnamed array allocated on the heap
```

```
allocate(first)
```

```
! now first refers to an unnamed type(atom_list) variable,  
! allocated on the heap
```

- ▶ Unlike **allocatables**, once allocated the **pointers** may be migrated to other targets

- ▶ If you allocate a pointer, an unnamed object of the pointee type is created, and associated with the pointer itself

```
real, dimension(:, :, :), pointer :: r  
type(atom_list), pointer :: first
```

```
allocate(r(5, 15, 6))
```

```
! now r refers an unnamed array allocated on the heap
```

```
allocate(first)
```

```
! now first refers to an unnamed type(atom_list) variable,  
! allocated on the heap
```

- ▶ Unlike **allocatables**, once allocated the **pointers** may be migrated to other targets
- ▶ You can use pointer allocation in place of allocatable, but, unless necessary, prefer **allocatable**: the compiler usually optimizes better

- ▶ If you allocate a pointer, an unnamed object of the pointee type is created, and associated with the pointer itself

```
real, dimension(:, :, :), pointer :: r  
type(atom_list), pointer :: first
```

```
allocate(r(5, 15, 6))
```

```
! now r refers an unnamed array allocated on the heap
```

```
allocate(first)
```

```
! now first refers to an unnamed type(atom_list) variable,  
! allocated on the heap
```

- ▶ Unlike **allocatables**, once allocated the **pointers** may be migrated to other targets
- ▶ You can use pointer allocation in place of allocatable, but, unless necessary, prefer **allocatable**: the compiler usually optimizes better
- ▶ You can deallocate the pointee by specifying the pointer in a **deallocate** statement

- ▶ In alternative to **target** variables, allocated pointers may be practically used as targets

- ▶ In alternative to `target` variables, allocated pointers may be practically used as targets
- ▶ Structure components can be pointers

- ▶ In alternative to **target** variables, allocated pointers may be practically used as targets
- ▶ Structure components can be pointers
- ▶ And a pointer in a structure can point to a structure of the same type:

```

type atom_list
  type(atom) :: a
  type(atom_list), pointer :: next
end type
  
```

which comes in handy to define complex data structures, like lists

BIG Mistakes with Pointers

- ▶ Referencing an undefined pointer (strange things may happen, it may also seem to work)
 - ▶ Good practice: initialize pointers to `nullptr` ()

- ▶ Referencing an undefined pointer (strange things may happen, it may also seem to work)
 - ▶ Good practice: initialize pointers to `NULL` ()
- ▶ Referencing a nullified pointer
 - ▶ Your program will fail
 - ▶ Which is better than messing up with memory

- ▶ Referencing an undefined pointer (strange things may happen, it may also seem to work)
 - ▶ Good practice: initialize pointers to `nullptr`
- ▶ Referencing a nullified pointer
 - ▶ Your program will fail
 - ▶ Which is better than messing up with memory
- ▶ Changing association of an allocated pointer
 - ▶ This is a memory leak, and programmers causing memory leaks have really bad reputation

- ▶ Referencing an undefined pointer (strange things may happen, it may also seem to work)
 - ▶ Good practice: initialize pointers to `null()`
- ▶ Referencing a nullified pointer
 - ▶ Your program will fail
 - ▶ Which is better than messing up with memory
- ▶ Changing association of an allocated pointer
 - ▶ This is a memory leak, and programmers causing memory leaks have really bad reputation
- ▶

```

real, dimension(:, :), pointer :: r, p
!...
allocate(r(n,m))
p => r
! ...
deallocate(r)
p(k,1) = p(k,1)+1
      
```

Now you'll be in troubles with `p`, with really strange behavior

- ▶ Discretization on Cartesian 2D grid with Dirichlet Boundary Conditions

$$\begin{cases}
 f(x_{i+1,j}) + f(x_{i-1,j}) - 2f(x_{i,j}) + \\
 f(x_{i,j+1}) + f(x_{i,j-1}) - 2f(x_{i,j}) = 0 & \forall x_{i,j} \in (a, b)^2 \\
 f(x_{i,j}) = \alpha(x_{i,j}) & \forall x_{i,j} \in \partial[a, b]^2
 \end{cases}$$

- ▶ Iterative advancement using Jacobi method

$$\begin{cases}
 f_{n+1}(x_{i,j}) = \frac{1}{4} [& f_n(x_{i+1,j}) + f_n(x_{i-1,j}) + \\
 & f_n(x_{i,j+1}) + f_n(x_{i,j-1})] & \forall n > 0 \\
 f_0(x_{i,j}) = 0 & \forall x_{i,j} \in (a, b)^2 \\
 f_n(x_{i,j}) = \alpha(x_{i,j}) & \forall x_{i,j} \in \partial[a, b]^2, & \forall n > 0
 \end{cases}$$

```

program laplace

 integer :: nx, ny, nz

 type(meshpoint), dimension(:,:,:), allocatable :: coords

 type(normal), dimension(:,:,:), allocatable :: xnormals
 type(normal), dimension(:,:,:), allocatable :: ynormals
 type(normal), dimension(:,:,:), allocatable :: znormals

 real(rk), dimension(:,:,:), allocatable :: volumes
end type
!...
type(mesh) :: my_mesh

! allocate my_mesh components with extents nx, ny, nz
! immediately checking for failures!
```

# A Recurrent Issue, Again

```
► real(rk) :: x(NX,NY,NZ)
 real(rk) :: y(NX,NY,NZ)
 real(rk) :: z(NX,NY,NZ)
```

Or

```
type meshpoint
 real(rk) :: x, y, z
end type
```

```
type(meshpoint), dimension(NX,NY,NZ) :: coords
```

Which one is best?

## A Recurrent Issue, Again

- ▶ `real(rk) :: x(NX,NY,NZ)`  
`real(rk) :: y(NX,NY,NZ)`  
`real(rk) :: z(NX,NY,NZ)`

Or

```
type meshpoint
```

```
 real(rk) :: x, y, z
```

```
end type
```

```
type(meshpoint), dimension(NX,NY,NZ) :: coords
```

Which one is best?

- ▶ Again, both have merits

# A Recurrent Issue, Again

- ▶ `real(rk) :: x(NX,NY,NZ)`  
`real(rk) :: y(NX,NY,NZ)`  
`real(rk) :: z(NX,NY,NZ)`

Or

```
type meshpoint
 real(rk) :: x, y, z
end type
```

```
type(meshpoint), dimension(NX,NY,NZ) :: coords
```

Which one is best?

- ▶ Again, both have merits
  - ▶ The former (if done properly) allows hardware to play efficient tricks in memory accesses

## A Recurrent Issue, Again

- ▶ `real(rk) :: x(NX,NY,NZ)`  
`real(rk) :: y(NX,NY,NZ)`  
`real(rk) :: z(NX,NY,NZ)`

Or

```
type meshpoint
 real(rk) :: x, y, z
end type
```

```
type(meshpoint), dimension(NX,NY,NZ) :: coords
```

Which one is best?

- ▶ Again, both have merits
  - ▶ The former (if done properly) allows hardware to play efficient tricks in memory accesses
  - ▶ The latter brings in cache all values related to a grid point as soon as one component is accessed

# A Recurrent Issue, Again

- ▶ `real(rk) :: x(NX,NY,NZ)`  
`real(rk) :: y(NX,NY,NZ)`  
`real(rk) :: z(NX,NY,NZ)`

Or

```
type meshpoint
 real(rk) :: x, y, z
end type
```

```
type(meshpoint), dimension(NX,NY,NZ) :: coords
```

Which one is best?

- ▶ Again, both have merits
  - ▶ The former (if done properly) allows hardware to play efficient tricks in memory accesses
  - ▶ The latter brings in cache all values related to a grid point as soon as one component is accessed
- ▶ Here, we lean to the latter

# A Recurrent Issue, Again

- ▶ `real(rk) :: x(NX,NY,NZ)`  
`real(rk) :: y(NX,NY,NZ)`  
`real(rk) :: z(NX,NY,NZ)`

Or

```
type meshpoint
 real(rk) :: x, y, z
end type
```

```
type(meshpoint), dimension(NX,NY,NZ) :: coords
```

Which one is best?

- ▶ Again, both have merits
  - ▶ The former (if done properly) allows hardware to play efficient tricks in memory accesses
  - ▶ The latter brings in cache all values related to a grid point as soon as one component is accessed
- ▶ Here, we lean to the latter
  - ▶ As in most numerical schemes,  $x$ ,  $y$ , and  $z$  components of the same mesh point are accessed together

# Multiblock Meshes and More

  - ▶ Like lists
  - ▶ Like binary trees, oct-trees, n-ary trees

# If You Read Code Like This...

```
type block_item
 type(block), pointer :: this_block

 type(block_item), pointer :: next
end type

!...
do while (associated(p))
 call advance_block_in_time(p%this_block)
 p => p%next
end do
```

```
type block_item
 type(block), pointer :: this_block

 type(block_item), pointer :: next
end type

!...
do while (associated(p))
 call advance_block_in_time(p%this_block)
 p => p%next
end do
```

- ▶ It is processing a singly-linked list of mesh blocks
- ▶ You know how to handle it, now

# And If You Read Code Like This...

```

type block_tree_node
 type(block), pointer :: this_block

 integer :: children_no
 type(block_tree_node), pointer :: childrens

 type(block_tree_node), pointer :: next_sibling
end type

!...
recursive subroutine tree_advance_in_time(n)
 type(block_tree_node) :: n
 type(block_tree_node), pointer :: p
 integer :: i

 p => n%childrens
 do i=0,n%children_no
 call tree_advance_in_time(p)
 p => p%next_sibling
 end do

 call advance_block_in_time(n%this_block)
end subroutine tree_advance_in_time

```

# And If You Read Code Like This...

```

type block_tree_node
 type(block), pointer :: this_block

 integer :: children_no
 type(block_tree_node), pointer :: childrens

 type(block_tree_node), pointer :: next_sibling
end type

!...
recursive subroutine tree_advance_in_time(n)
 type(block_tree_node) :: n
 type(block_tree_node), pointer :: p
 integer :: i

 p => n%childrens
 do i=0,n%children_no
 call tree_advance_in_time(p)
 p => p%next_sibling
 end do

 call advance_block_in_time(n%this_block)
end subroutine tree_advance_in_time

```

- ▶ It is processing a tree of mesh blocks (AMR, probably)
- ▶ You need to learn more on abstract data structures
- ▶ Don't be afraid, it's not that difficult

Extending the Language

Managing Memory

Dynamic Memory Allocation

Fortran Pointers

Sketchy Ideas on Data Structures

**Bridging the Gap with C**

Conclusions

- ▶ You may want to call a C function from a Fortran program
- ▶ Or call a Fortran procedure from a C program
- ▶ And you don't want to translate and re-debug
- ▶ Or you can't, as you don't have sources
  
- ▶ You may also want to share global data among C and Fortran program units
  
- ▶ This has been done in the past with non-standard tricks
- ▶ Fortran 2003 offers a better, standard way
- ▶ Let's look at it in steps

- Imagine you have this C function:

```
double avg_var(int n, const double a[], double *var) {
 double avg = 0.0;
 double avg2 = 0.0;
 for(int i=0;i<n;i++) {
 avg += a[i];
 avg2 += a[i]*a[i];
 }
 avg = avg/n;
 *var = avg2/n - avg*avg;
 return avg;
}
```

and you want to call it from your Fortran code like:

```
avg = avg_var(m,b,var)
```

- Imagine you have this C function:

```
double avg_var(int n, const double a[], double *var) {
 double avg = 0.0;
 double avg2 = 0.0;
 for(int i=0;i<n;i++) {
 avg += a[i];
 avg2 += a[i]*a[i];
 }
 avg = avg/n;
 *var = avg2/n - avg*avg;
 return avg;
}
```

and you want to call it from your Fortran code like:

```
avg = avg_var(m,b,var)
```

- Or you have your favorite, thoroughly tested Poisson solver:

```
interface
 subroutine myPoissonSolver(l, m, n, f)
 integer, intent(in) :: l, m, n
 real(kind(1.0D0)), intent(inout) :: f(l,m,n)
 end subroutine myPoissonSolver
end interface
```

and you want to call it from your C code like:

```
myPoissonSolver(nx, ny, nz, field);
```

- ▶ We could think that Fortran interfaces and C declarations are enough

- ▶ And write, to call C from Fortran:

```

interface
 function avg_var(n, a, var)
 integer, intent(in) :: n
 real(kind(1.0D0)), intent(in) :: a(*)
 real(kind(1.0D0)), intent(out) :: var
 real(kind(1.0D0)) :: avg_var
 end function avg_var
end interface

```

- ▶ And to call Fortran from C, add on Fortran side:

```

interface
 subroutine myPoissonSolver(l, m, n, f)
 integer, intent(in) :: l, m, n
 real(kind(1.0D0)), intent(inout) :: f(l,m,n)
 end subroutine myPoissonSolver
end interface

```

and on the C side, the declaration:

```
void myPoissonSolver(int nx, int ny, int nz, field[nz][ny][nx]);
```

- ▶ This is the right track, but still half way from our destination

## Thou Shalt Not Mangle Names

- ▶ Fortran compilers mangle procedure names
  - ▶ All uppercase or all lowercase
  - ▶ Compilers may append/prepend one or two `_` characters
  - ▶ And for module procedures is even worse
  - ▶ Used to be sorted out on the C side, in non-portable ways

## Thou Shalt Not Mangle Names

- ▶ Fortran compilers mangle procedure names
  - ▶ All uppercase or all lowercase
  - ▶ Compilers may append/prepend one or two `_` characters
  - ▶ And for module procedures is even worse
  - ▶ Used to be sorted out on the C side, in non-portable ways
- ▶ Enter Fortran 2003 `bind` attribute

## Thou Shalt Not Mangle Names

- ▶ Fortran compilers mangle procedure names
  - ▶ All uppercase or all lowercase
  - ▶ Compilers may append/prepend one or two `_` characters
  - ▶ And for module procedures is even worse
  - ▶ Used to be sorted out on the C side, in non-portable ways
- ▶ Enter Fortran 2003 `bind` attribute
- ▶ For C to Fortran:

```
interface
 function avg_var(n, a, var) bind(c)
 integer, intent(in) :: n
 real(kind(1.0D0)), intent(in) :: a(*)
 real(kind(1.0D0)), intent(out) :: var
 real(kind(1.0D0)) :: avg_var
 end function avg_var
end interface
```

- ▶ Fortran compilers mangle procedure names
  - ▶ All uppercase or all lowercase
  - ▶ Compilers may append/prepend one or two `_` characters
  - ▶ And for module procedures is even worse
  - ▶ Used to be sorted out on the C side, in non-portable ways

▶ Enter Fortran 2003 **bind** attribute

▶ For C to Fortran:

```

interface
 function avg_var(n, a, var) bind(c)
 integer, intent(in) :: n
 real(kind(1.0D0)), intent(in) :: a(*)
 real(kind(1.0D0)), intent(out) :: var
 real(kind(1.0D0)) :: avg_var
 end function avg_var
end interface

```

▶ For Fortran to C, Fortran side:

```

interface
 subroutine myPoissonSolver(l, m, n, f) bind(c)
 integer, intent(in) :: l, m, n
 real(kind(1.0D0)), intent(inout) :: f(l,m,n)
 end subroutine myPoissonSolver
end interface

```

and on the C side, the declaration:

```
void myPoissonSolver(int nx, int ny, int nz, field[nz][ny][nx]);
```

## Thou Shalt Care for Argument Passing

- ▶ Fortran passes arguments by reference
  - ▶ Under the hood, it's like a C pointer
  - ▶ Works for C arrays and pointers to scalar variables
  - ▶ But usually scalars are passed by value in C

## Thou Shalt Care for Argument Passing

- ▶ Fortran passes arguments by reference
  - ▶ Under the hood, it's like a C pointer
  - ▶ Works for C arrays and pointers to scalar variables
  - ▶ But usually scalars are passed by value in C
- ▶ Enter Fortran 2003 `value` attribute

 integer, value :: n
 real(kind(1.0D0)), intent(in) :: a(*)
 real(kind(1.0D0)), intent(out) :: var
 real(kind(1.0D0)) :: avg_var
 end function avg_var
end interface

```

- ▶ For Fortran to C, Fortran side:

```

interface
 subroutine myPoissonSolver(l, m, n, f) bind(c)
 integer, value :: l, m, n
 real(kind(1.0D0)), intent(inout) :: f(l,m,n)
 end subroutine myPoissonSolver
end interface

```

and on the C side, still the declaration:

```
void myPoissonSolver(int nx, int ny, int nz, field[nz][ny][nx]);
```

- ▶ Fortran is quite liberal on data sizes
  - ▶ Implementations have a lot of freedom
  - ▶ And C is also quite liberal

- ▶ Fortran is quite liberal on data sizes
  - ▶ Implementations have a lot of freedom
  - ▶ And C is also quite liberal
  
- ▶ Enter Fortran 2003 `iso_c_binding` module

- ▶ Fortran is quite liberal on data sizes
  - ▶ Implementations have a lot of freedom
  - ▶ And C is also quite liberal
- ▶ Enter Fortran 2003 `iso_c_binding` module
- ▶ For C to Fortran:

```
interface
 function avg_var(n, a, var) bind(c)
 use iso_c_binding
 integer(c_int), value :: n
 real(c_double), intent(in) :: a(*)
 real(c_double), intent(out) :: var
 real(c_double) :: avg_var
 end function avg_var
end interface
```

- ▶ Fortran is quite liberal on data sizes
  - ▶ Implementations have a lot of freedom
  - ▶ And C is also quite liberal
  
- ▶ Enter Fortran 2003 `iso_c_binding` module

- ▶ For C to Fortran:

```

interface
 function avg_var(n, a, var) bind(c)
 use iso_c_binding
 integer(c_int), value :: n
 real(c_double), intent(in) :: a(*)
 real(c_double), intent(out) :: var
 real(c_double) :: avg_var
 end function avg_var
end interface

```

- ▶ For Fortran to C, Fortran side:

```

interface
 subroutine myPoissonSolver(l, m, n, f) bind(c)
 use iso_c_binding
 integer(c_int), value :: l, m, n
 real(c_double), intent(inout) :: f(l,m,n)
 end subroutine myPoissonSolver
end interface

```

and on the C side, still the declaration:

```
void myPoissonSolver(int nx, int ny, int nz, field[nz][ny][nx]);
```

## More from `iso_c_binding`

- ▶ `iso_c_binding` defines named constants holding kind type parameter values for intrinsic types for the platform
- ▶ `integer(c_int)` is the kind value corresponding to a C `int`
- ▶ Negative values are used for unsupported C types, so the compiler will flag the problem

- ▶ A few of them:

| Type                   | Kind                          | C type                       |
|------------------------|-------------------------------|------------------------------|
| <code>integer</code>   | <code>c_int</code>            | <code>int</code>             |
|                        | <code>c_short</code>          | <code>short int</code>       |
| <code>real</code>      | <code>c_float</code>          | <code>float</code>           |
|                        | <code>c_double</code>         | <code>double</code>          |
| <code>complex</code>   | <code>c_float_complex</code>  | <code>float _Complex</code>  |
|                        | <code>c_double_complex</code> | <code>double _Complex</code> |
| <code>logical</code>   | <code>c_bool</code>           | <code>_Bool</code>           |
| <code>character</code> | <code>c_char</code>           | <code>char</code>            |

- ▶ Fortran 2008 adds `c_sizeof()`, check with your compiler!

- ▶ Fortran has multidimensional arrays
- ▶ C has arrays of arrays (of arrays...)
- ▶ Thus the mapping of array indexes to actual data layout in memory is inverted
  - ▶ Fortran array **a (L, M, N)**
  - ▶ maps to C array **a [N] [M] [L]**

- ▶ Fortran has multidimensional arrays

- ▶ **bind** also helps for derived types and global data
- ▶ For derived types, each component must be interoperable

Fortran

```

type, bind(c) :: particle
 integer(c_int) :: n
 real(c_float) :: x,y,z
 real(c_float) :: vx,vy,vz
end type particle

```

C

```

typedef struct particle {
 int n;
 float x,y,z;
 float vx,vy,vz;
} particle;

```

- ▶ For module variables or common blocks, use

Fortran

```

integer(c_long), bind(c) :: n

real(c_double) :: m,k
common /com_mk/ m,k
bind(c) :: /com_mk/

```

C

```

extern long n;

extern struct mk {
 double m, k;
} com_mk;

```

- ▶ Note: common blocks become C **structs**

# Fortran Pointers vs. C Pointers

- ▶ As of argument passing, not a problem
- ▶ But Fortran pointers are not interoperable with C
- ▶ Fortran pointers sport richer semantics, notably:
  - ▶ multidimensional arrays
  - ▶ non-contiguous memory areas
- ▶ C functions returning a pointer must have `type(c_ptr)` type (from `iso_c_binding`)
- ▶ Ditto for C pointer variables and pointer members of C `structs`:

## Fortran

```

type, bind(c) :: block
 integer(c_int) :: n_neighbors
 type(c_ptr) :: neighbors
 type(c_ptr) :: grid
end type block

```

## C

```

typedef struct {
 int n_neighbors;
 int *neighbors;
 mesh *grid;
} block;

```

- ▶ **iso\_c\_binding** module provides much needed help

- ▶ `iso_c_binding` module provides much needed help
- ▶ `c_loc(x)` returns a valid C pointer to the content of variable `x`
- ▶ `c_f_pointer(cptr, fptr[, shape])` performs the opposite translation, writing the result in the Fortran pointer `fptr`
  - ▶ An optional `shape` argument like `(/n/)` or `(/1,m,n/)` gives it a shape for array pointers

- ▶ `iso_c_binding` module provides much needed help
- ▶ `c_loc(x)` returns a valid C pointer to the content of variable `x`
- ▶ `c_f_pointer(cptr, fptr[, shape])` performs the opposite translation, writing the result in the Fortran pointer `fptr`
  - ▶ An optional `shape` argument like `(/n/)` or `(/1,m,n/)` gives it a shape for array pointers
- ▶ If `f_proc` is an interoperable Fortran procedure, `c_funloc(f_proc)` returns a valid C pointer (`type(c_funptr)`) to it
- ▶ `c_f_procpointer(cfptr, fpptr)` performs the opposite translation, writing the result in the Fortran procedure pointer `fpptr`

- ▶ Obviously, C and Fortran sources must be separately compiled and then linked

```
user@cineca$> gcc -c fun_cmd.c
user@cineca$> gfortran -c main_cmd.f90
user@cineca$> gfortran fun_cmd.o main_cmd.o -o main_cmd
```

- ▶ Easy, if calling C functions from a Fortran program
  - ▶ Fortran Runtime Library is usually built on top of C one

- ▶ Obviously, C and Fortran sources must be separately compiled and then linked

```
user@cineca$> gcc -c fun_cmd.c
user@cineca$> gfortran -c main_cmd.f90
user@cineca$> gfortran fun_cmd.o main_cmd.o -o main_cmd
```

- ▶ Easy, if calling C functions from a Fortran program
  - ▶ Fortran Runtime Library is usually built on top of C one
- ▶ Less so if calling Fortran procedures from a C program
  - ▶ Fortran compiler might insert calls to its Runtime Library
- ▶ Best practice:

```
user@cineca$> gcc -lgfortran procedures.o main.c
```

- ▶ Your mileage may vary, browse your compiler manuals

## ► Write the Fortran interface to C qsort

```

module qsort_c_to_fortran
 use iso_c_binding
 integer, parameter :: sp = kind(1.0)
 interface
 !Write the Fortran interface to C qsort!
 !void qsort(void *base,
 ! size_t nmemb,
 ! size_t size,
 ! int (*compar)(const void *,const void *));
 end interface
contains
 function compare_reals(a,b) bind(c)
 integer(c_int) :: compare_reals
 real(c_float) :: a,b
 if(a>b) then
 compare_reals=1
 else if(a<b) then
 compare_reals=-1
 else
 compare_reals=0
 endif
 end function compare_reals
end module qsort_c_to_fortran

program test_qsort_c
 use qsort_c_to_fortran
 integer(c_size_t), parameter :: n=7
 real(c_float), pointer :: a(:)

 allocate(a(n))
 call random_number(a)
 print*, 'Unordered a: '
 print*, a

 call qsort(c_loc(a(1)), n, c_sizeof(a(1)), &
 c_funloc(compare_reals));

 print*, 'Ordered a: '
 print*, a

end program test_qsort_c

```

Extending the Language

Managing Memory

Conclusions

- ▶ More Fortran practice
  - ▶ Time was tight, and that's your job

- ▶ More Fortran practice
  - ▶ Time was tight, and that's your job
- ▶ More about programming
  - ▶ Code development management tools
  - ▶ Debugging tools
  - ▶ Look among CINECA HPC courses

- ▶ More Fortran practice
  - ▶ Time was tight, and that's your job
- ▶ More about programming
  - ▶ Code development management tools
  - ▶ Debugging tools
  - ▶ Look among CINECA HPC courses
- ▶ More Fortran
  - ▶ Full object oriented programming
  - ▶ Floating point environment
  - ▶ Direct I/O
  - ▶ Asynchronous I/O
  - ▶ Submodules
  - ▶ Even more format edit descriptors
  - ▶ A few more statements and quite a few intrinsics
  - ▶ Coarrays
